Abstract   Poore, G.C.B. (2021). Indo-West Pacific and Australian species of Eucalliacidae with descriptions of four new species (Crustacea: Axiidea). *Memoirs of Museum Victoria* 80: 1–41.

Surveys of coral reefs and sandy shallow environments in the Indo-West Pacific and Australia have discovered 14 species of Eucalliacidae, of which four are new. All species are diagnosed, and *Andamancalliax arafura* sp. nov., *Eucalliaxiopsis dworschaki* sp. nov., *Eucalliaxiopsis paradoxa* sp. nov. and *Eucalliaxiopsis patio* sp. nov. are described as new. The collection is an opportunity to re-diagnose other species and provide colour photographs of some. *Calliaxina xishaensis* Liu and Liang, 2016, is synonymised with *Calliaxina novaebritanniae* (Borradaile, 1900).

Keywords   Crustacea, Axiidea Eucalliacidae, taxonomy, new species

Introduction

Of eight families of callianassid-like Axiidea, Eucalliacidae have the most complicated taxonomic history that was most recently reviewed by Poore et al. (2019). Their revision and the molecular phylogeny on which it was based (Robles et al. 2020) depended in part on extensive collections made in the Indo-West Pacific over the last couple of decades. These collections also made it possible to re-diagnose known species and describe others revealed as new during the molecular study.

Eucalliacidae comprise seven genera, diagnosed by Poore et al. (2019), and 21 species listed by these authors. Six species are from the Atlantic or Mediterranean and two are deep-sea. This contribution deals only with those from coral reefs and shallow environments in the Indo-West Pacific and Australia. Fourteen species are covered here, of which four are described as new.

Methods

Much of the material comes from the Muséum nationale d'Histoire naturelle, Paris (MNHN), including expeditions to Papua New Guinea, Madang Province (PAPUA NIUGINI stations), and New Ireland Province (KAVIENG 2014 stations). Another sizable Indo-West Pacific collection has been accumulated by the Florida Museum of Natural History, University of Florida (UF). Specimens were also examined from Museums Victoria, Melbourne (NMV); the Australian Museum, Sydney (AM); Western Australian Museum, Perth (WAM); and Naturhistorisches Museum, Vienna (NHMW).

Unless otherwise stated, station prefixes and numbers belong to systems initiated by the museum holding the material.

Size is expressed as carapace length (cl.), including rostrum, in mm. Individuals marked with an asterisk (*) were sequenced and contributed to molecular analysis (Robles et al., 2020). Diagnoses have been prepared for all species and coded into a DELTA database (Dallwitz, 2010). This database was used to generate the diagnoses presented here; character states in italics diagnose each species in at least one respect from every other species. Colour photographs of fresh specimens were taken in the laboratory shortly after collection by Arthur Anker and Zdeněk Ďuriš. Photographs in figs 12 and 25 were taken using a Leica 205C microscope and the Leica Application Suite multifocus routine.

Eucalliacidae Manning and Felder, 1991

Eucalliinae Manning and Felder, 1991: 781 (misspelling).
Eucalliacinae Sakai, 1999: 108–109.—Sakai, 2018: 734–738 (partim).
Eucalliacidae.—Sakai, 2011: 491.—Sakai and Türkay, 2014: 190 (outdated key to genera).—Sakai, 2018: 734–738.—Poore et al., 2019: 122 (for complete synonymy).

Remarks. The family was diagnosed by Poore et al. (2019). It is recognised most easily by the truncate setose apex of the dactylus of maxilliped 3. Callianopsidae, which also share this feature, differ in that the uropodal exopod lacks a dorsal plate, indicated in eucalliacids by a secondary dense row of stout setae diverging on the upper surface from the anterior margin.

Andamancalliax Sakai, 2011

Andamancalliax Sakai, 2011: 494–495.—Sakai, 2018: 738.—Poore et al., 2019: 126.

Remarks. The genus differs from other eucalliacids in the prominent sharp rostrum and the unequal dissimilar chelipeds, the minor one having elongate fingers. The crista dentata of the type species was not illustrated, but in the new species described here, it comprises few sharp long spines in lieu of a row of similar even teeth seen in other genera. Sakai (2011, 2018) stated that the maxilliped 3 lacks an exopod but in the newly discovered female of what appears to be a different species, a small exopod is present. The genus was diagnosed by Sakai (2011) as having the male pleopod 1 biarticulate, but this was changed by Sakai (2018) to pleopod 1 absent. I believe it is biarticulate, as in other eucalliacids, for the reasons given under remarks on the type species.

Andamancalliax andamanica (Sakai, 2002)

Calliax andamanica Sakai, 2002: 463–467, figs 1, 2.—Sakai, 2005: 201.
Andamancalliax andamanica Sakai, 2011: 495.—Sakai, 2018: 738.

Distribution. Thailand, Andaman Sea. Shelf, 31–61 m.

Remarks. Sakai (2002) referred to the holotype of *Calliax andamanica* as female in the description and male in the figure legends. His figure 2B of the "female Plp 1" from the holotype, described as "uniramous, two-articled, distal article bilobed distally", is most probably from an immature male (cf. fig. 16q of male pleopod 1 of *Eucalliaxiopsis dworschaki* sp. nov.).

Andamancalliax arafura sp. nov.

http://zoobank.org/urn:lsid:zoobank.org:act:1E5B7D96-E101-45B8-AD22-7156C8B29B30

Figures 2, 3

Material examined. Holotype. Australia, NT, Arafura Sea, 9.2055° S, 133.6483° E, 155–158 m, oozy mud (RV *Southern Surveyor* stn 032BS006), AM P.74526 (female, 3.7 mm, without major cheliped).

Description of holotype. Carapace smooth; gastric–abdominal regions together 4.3 times as long as width of these regions together; branchiostegite fully calcified; cervical groove at 0.62 carapace length, scarcely obvious on branchiostegite.

Rostrum acute, strongly tapering, two-thirds length of eyestalk. Anterolateral carapace lobe absent. Thoracic sternite 7 1.6 times as long as wide, with well-defined median sulcus over posterior half, smooth over medial half, weak lateral ridge anterior to coxal articulation crossing pit at quarter of width.

Pleonite 1 without anterior transverse groove, without sternal plates.

Eyestalk 1.8 times as long as greatest width, swollen laterally, tapering distally around cornea, with defined apical lobe; cornea wider than long. Antennular peduncle 1.8 times as long as width of both eyestalks; article 2 twice as long as wide; article 3 as long as article 2; article 3 with ventrolateral row of few setae, continued onto flagellum. Antennal peduncle 2.2 times as long as width of both eyestalks, overreaching antennule peduncle by most of article 5; scaphocerite ovoid, longer than wide; article 4

c. 5 times as long as wide; article 5 0.7 length of article 4. Maxilliped 3 basis with 4 mesial teeth along lower margin, ischium with strongly expanded proximo-lower lobe, tapering to two-thirds of its greatest proximal width; crista dentata of 3 short basal spines, plus 4 long sharp spines, first 2 recurved, last 2 overlapping merus; merus upper margin 1.5 times as long as greatest width; carpus–dactylus together reaching back to mid-ischium; dactylus as wide as long, with setose truncate apex; exopod third length of upper margin of ischium.

Major cheliped missing. Minor cheliped (right) ischium c. 2.8 times as long as distal width, lower margin with sharp subdistal spine; merus twice as long as broad, lower margin convex, unarmed; carpus 1.1 times as wide as upper length, margins carinate; propodus palm tapering, 0.9 times as wide as upper palm length, upper margin rounded, distomesial margin of palm oblique, distolateral margin of palm oblique, with triangular tooth at base of finger; fixed finger twice length of upper margin of palm, lateral cutting edge with proximal sharp oblique tooth, obtuse distal tooth; dactylus as long as fixed finger, 5 times as long as wide at base, cutting edge with obtuse rounded tooth at about two-thirds.

Pereopod 2 merus 2.2 times as long as maximum width; dactylus c. 5 times as long as upper margin of propodus. Pereopod 3 merus 2.3 times as long as maximum width; carpus 1.7 times as long as wide; propodus with lower margin concave, 1.3 times as long as mid-length; dactylus less than half as long as axial length of propodus. Pereopod 4 merus 3 times as long as maximum width; carpus 3 times as long as wide; propodus setose, with long distal spiniform seta among setose margin, as long as dactylus, with 2 long distal setae overlapping dactylus. Pereopod 5 chelate.

Pleopod 1 uniarticulate, tapering. Pleopod 2 endopod 2.6 times as long as wide; appendix interna at midpoint of endopod, reaching two-thirds remaining length of endopod. Pleopod 3 with appendix interna embedded in endopod.

Uropodal endopod ovoid, anterior margin more convex than posterior margin, widest at midpoint, 1.7 times as long as wide, without facial setae; exopod ovate, greatest dimension 1.6 times anterior margin, anterior margin straight, curving into distal margin, sharper curve between distal and posterior margins, with row of blade-like setae on distal posterior margin; dorsal plate defined by weak longitudinal ridge, extending half of exopod width, distal plate margin with a dozen scattered spiniform setae of various sizes. Telson 1.6 times as wide as long, broadest over anterior half, lateral margin evenly curving to posterior margin; posterior margin convex, with posterolateral clusters of long setae; dorsal surface smooth.

Etymology. For the Arafura Sea (noun in apposition).

Distribution. Australia, Arafura Sea. Shelf, 151–158 m.

Remarks. The truncate setose dactylus of maxilliped 3, presence of a dorsal plate, spike-like rostrum and long fingers on the minor cheliped place the new species in *Andamancalliax*. The sole specimen differs from the illustrations of *A. andamanica* in the presence of a short exopod on maxilliped 3, a distal spine on the lower margin of the ischium of the minor cheliped, a tooth on the fixed finger of the minor cheliped, a

Figure 1. Live colour photographs: a, *Calliaxina bulimba*, Papua New Guinea. MNHN-IU-2013-7097; b, c, *C. kensleyi*, Saudi Arabia, UF 36699; d, e, *C. novaebritanniae*, Papua New Guinea, MNHN-IU-2013-7062; f, *Eucalliaxiopsis dworschaki*, French Polynesia, UF 16286; g, *E. dworschaki*, Papua New Guinea, MNHN-IU-2013-7081; h, *E. inaequimana*, French Polynesia, UF 29162; i, *E. inaequimana*, French Polynesia, UF 29208. Photos a, d, e, g: Z. Ďuriš; b, c, f, h, i, A. Anker. Various scales.

more oval uropodal endopod and a less pronounced dorsal plate on the uropodal exopod. The few sharp spines that constitute the crista dentata are unique within Eucalliacidae; the situation in *A. andamanica* was not reported. The dorsal plate of the uropodal exopod of *A. arafura* is less well developed than in *A. andamanica*, which was said to have the dorsal surface carinate and the anterior half elevated.

Calliaxina Ngoc-Ho, 2003

*Calliaxina* Ngoc-Ho, 2003: 493–494.—Sakai, 2011: 497 (part).—Poore et al., 2019: 126–127.

Figure 2. *Andamancalliax arafura* sp. nov. Holotype, Australia, NT, A M P.74526 (female, 3.7 mm): a, b, anterior carapace, eyestalks, antennule, antenna, pleonite 1, dorsal, lateral views; c, pleonite 6, telson, uropod (c', detail of uropod exopod spiniform setae); d, thoracic sternite 7; e, f, minor cheliped (right), mesial, lateral views; g, pereopod 2; h, pereopod 3; i, j, pereopod 4, with detail of propodus, dactylus; k, pereopod 5. Scale bars = 1 mm.
Figure 3. *Andamancalliax arafura* sp. nov. Holotype, Australia, NT, A M P.74526 (female, 3.7 mm): a, b, left maxilliped 3, lateral, mesial views; c, left maxilliped 3, basis, merus, posterior view; d, pleonal sternite 1, pleopod 1; e, f, pleopods 2, 3. Scale bar = 1 mm.

Remarks. Calliaxina differs from *Eucalliaxiopsis* in lacking a transverse ridge on the telson, lacking differentiation between male and female major chelipeds, and always possessing an exopod on maxilliped 3, sometimes vestigial (Poore et al., 2019; Robles et al., 2020).

Calliaxina includes the type species, *C. punica* (de Saint Laurent and Manning, 1982) from the western Mediterranean plus four species from the Indo-West Pacific. Separation of the species is difficult because characters defining each have historically been incompletely documented. Juveniles of all species tend to have larger eyes, more acute rostrums and similar telsons, making differentiation on the basis of these characters impossible. Adult males of four species are known; juvenile males of one of these and of the fifth species have presumably immature pleopods 1 (see Poore et al. [2019] and discussions below under *C. bulimba* and *C. novaebritanniae*). Liu and Liang's (2016) key to species included one species here placed in *Eucalliaxiopsis* and relied on the shape of the rostrum and telson, both size-dependent features.

Key to species of *Calliaxina*

1. Maxilliped 3 exopod vestigial 2

– Maxilliped 3 exopod reaching at least third way along ischium 3

2. Major cheliped propodus distomesial margin with setae aligned in 2 groups of c. 10 and c. 6 setae; minor cheliped distomesial margin with setae aligned in 2 scarcely separate groups of c. 20 and c. 8 setae; cheliped merus lower margin with few denticles; Red Sea, Jordan, Saudi Arabia; Madagascar .... *C. kensleyi* (Dworschak, 2005)

– Major and minor chelipeds propodi distomesial margins with setae aligned in 2 groups of c. 9 setae each; cheliped merus lower margin with 2 or 3 proximal truncated curved teeth and diminishing denticles more distally; Papua New Guinea, SE Australia .... *C. bulimba* (Poore and Griffin, 1979)

3. Maxilliped 3 exopod overlapping merus (except in juveniles) 4

– Maxilliped 3 exopod reaching half-way along ischium; male pleopod 1 article 2 3 times as long as wide; Japan, East China Sea .... *C. sakaii* (de Saint Laurent, 1979)

4. Antennule peduncle reaching base of antenna peduncle article 5; male pleopod 1 with broad subapical notch, prominent appendix interna, triangular apex; Mediterranean .... *C. punica* (de Saint Laurent and Manning, 1982)

– Antennule peduncle reaching midpoint of antenna peduncle article 5; pleopod 1 article 2 with narrow apical notch, short appendix interna, apex prominently curved; Papua New Guinea, Indonesia, NE Australia, Philippines, South China Sea, French Polynesia .... *C. novaebritanniae* (Borradaile, 1900)

Calliaxina bulimba (Poore and Griffin, 1979)

Figures 1a, 4, 5, 12a, h

> *Callianassa bulimba* Poore and Griffin, 1979: 257, fig. 21.
> *Calliax bulimba.*—de Saint Laurent and Manning, 1982: 222.—Sakai, 1999: 119, fig. 32a–c.—Sakai, 2005: 202.

> *Eucalliax kensleyi.*—Sakai, 2017: 1122–1124 (partim), fig. 2D.

Material examined. Australia. Qld, Britomart Reef front, 18° 17' S, 146° 38' E (NMV stn AIMS 57), NMV J12184 (female, 8.7 mm). Rib Reef, 18.48° S, 146.86° E, October 1985, shallow lagoon, 8 m, (M. Riddle stn R/10/1), NMV J71676 (male, 4.6 mm).

Papua New Guinea. Madang Province, lagoon, PAPUA NIUGINI stations: 05° 10.2' S, 145° 50.4' E, 1–3 m (stn PR243), MNHN-IU-2013-7097* (male, 4.5 mm); 05° 10.3' S, 145° 48.5' E, 1–18 m (stn PR213), MNHN-IU-2013-7124 (female, 3.5 mm).

Diagnosis. Sternite 7 with transverse groove visible only laterally, anteromedial lobe rounded. Antennule peduncle reaching to midpoint of antenna peduncle article 5. Maxilliped 3 exopod vestigial, about twice as long as wide. Major cheliped merus, lower margin with 2 or 3 proximal truncate teeth; propodus distomesial margin with setae aligned in 2 similar groups of c. 9 setae each. *Male pleopod 1 article 1 linear, with distal setae; article 2 short, oblique (juvenile form).*

Colour. Exoskeleton translucent white (fig. 1a).

Distribution. Indonesia, Ambon; Papua New Guinea, Madang and New Ireland provinces; Australia, Qld (type locality). Coral reef lagoon, 1–18 m.

Remarks. Poore and Griffin's (1979) simple figures are supplemented here by illustrations of a newly discovered male and female from Australia. The telson is widest proximally, the anterior margins each side of the rostrum are concave, and the distomesial margins of the propodi of the chelipeds bear two widely separate small groups of c. 9 setae each. As is typical of callianassid-like families, the rostrum of small individuals is more acute than in adults and the cornea more swollen. Separation of the anterior and posterior sections of thoracic sternite 7 is weak, with only a slight inclination laterally terminating in a sublateral pit; the posterolateral margin carries groups of c. 6, 7 and 9 long setae (fig. 12h). As figured by Dworschak (2005), pleonite 1 lacks obvious ventral plates but bears two short rows of three or four long setae anterior to the pleopods.

The 4.5-mm male from Papua New Guinea has a pleopod 1 with long distal setae on article 1 and a short simple oblique article 2 (fig. 5d). This is consistent with Poore and Griffin's (1979: fig. 21g) and Dworschak's (2005: fig. 5c, d) illustrations of the much larger holotype (cl. 10 mm) and resembles those of *Eucalliaxiopsis inaequimana* (see Dworschak, 2014: fig. 4j–l), *E. madagassa* (see Ngoc-Ho, 2014: fig. 2S, as *C. thomassini*) and *E. patio* sp. nov. Pleopod 1 of the 4.6-mm male from Australia differs in having a bilobed article 2 with a longitudinal crease and a separate appendix interna (fig. 5b). As argued by Poore et. al. (2019), this would appear to be an intermediate form tending towards the more typical eucalliacid male pleopod (e.g., fig. 7h, j). Undeveloped male pleopods 1 are also seen in small juveniles of *C. novaebritanniae* (see below).

The small specimens from Papua New Guinea can be distinguished from the holotype in having an apparently broader uropodal endopod (1.25 times as long as wide vs 1.4 times). They did not possess the fine granular lateral surface in the gape of the cheliped illustrated by Poore and Griffin (1979). Sakai (1999: fig. 32) showed the cobblestone pattern on the lower branchiostegite to be a little more extensive in the holotype from Queensland than on the new material from Papua New Guinea.

This is one of two species with a rudimentary exopod on maxilliped 3, overlooked by Poore and Griffin (1979) but noted on the holotype by Sakai (1999). The exopod bears a few short setae. The other is *C. kensleyi* (Dworschak, 2005); the two were differentiated by Dworschak (2005) but see further comments under *C. kensleyi* below.

Sakai (2017) listed and figured an ovigerous female from Ambon, Indonesia, as *Eucalliax kensleyi* but on biogeographical grounds this is certainly *C. bulimba*.

Calliaxina kensleyi (Dworschak, 2005)

Figures 1b, c, 6, 7, 12b, c, i

> *Eucalliax kensleyi* Dworschak, 2005: 205, figs 1–4, 5a, b.—Sakai, 2017: 1122–1124 (partim), fig. 2A–C, E–G.
> *Calliaxina kensleyi.*—Poore et al., 2019: 125, 127, 146, fig. 19i.

Material examined. Saudi Arabia, Farasan Banks, Marka Island, sandy cay, 18.22055° N, 41.32438° E (stn SAFA-010), UF 36699 (male, 5.9 mm).

Madagascar, Tuléar (now Toliara), Thomassin stn 648, MNHN-IU-2014-10476 (female, 7.8 mm); Thomassin stn 650, MNHN-IU-2016-8086 (female, 6.6 mm). Nosy Bé, MNHN-IU-2016-8084 (male, 7.4 mm).

Diagnosis. Sternite 7 with transverse groove visible only laterally, anteromedial lobe rounded. Antennule peduncle reaching to midpoint of antenna peduncle article 5. *Maxilliped 3 exopod vestigial, about twice as long as wide.* Major cheliped merus, lower margin with 2 or 3 proximal truncate teeth; *propodus distomesial margin with setae aligned in 2 groups of c. 10 and c. 6 setae.* Male pleopod 1 article 2 about 2.5 times as long as wide; appendix interna obsolete.

Colour. Exoskeleton mostly translucent white, gastric region, epistome, upper parts of chelipeds pink (fig. 1b, c).

Distribution. Red Sea (Jordan, Saudi Arabia); western Indian Ocean (Madagascar). Intertidal, shallow sediments.

Remarks. Calliaxina kensleyi shares a vestigial maxilliped 3 exopod with *C. bulimba*. The two species were compared by Dworschak (2005) but the differences he listed are subtle and deserve reinterpretation and addition. The more pronounced rostrum of *C. kensleyi* is subtly so, but juveniles appear to have sharper rostrum in both species. The telson of *C. kensleyi* was
Figure 4. *Calliaxina bulimba*. Australia, Qld, NMV J12184 (female, 8.7 mm): a, anterior carapace, eyestalks, antennule, antenna; b, telson, uropod; c, thoracic sternite 7; d, pleonal sternite 1; e, maxilliped 3; f, g, major cheliped (right), mesial, lateral views; h, minor cheliped (left), mesial view; uropod. Scale bars = 1 mm.
Figure 5. *Calliaxina bulimba*. Australia, Qld, NMV J71676 (male, 4.6 mm): a, left coxa 5, pleonite 1, pleopod 1 in situ, lateral view; b, c, pleopods 1, 2. Papua New Guinea, MNHN-IU-2013-7097 (male, cl. 4.5 mm): d, e, pleopods 1, 2. Scale bars = 1 mm.

said to be widest at its midpoint, whereas that of *C. bulimba* is widest anteriorly; this difference is less obvious in smaller specimens. The uropodal exopod is oval in *C. kensleyi*, more tapering in *C. bulimba*, but again less clear in smaller specimens. In both species, the major cheliped (the slightly wider one) has a tooth on the fixed finger, whereas the minor cheliped does not, with the apparent exception of the paratype of *C. kensleyi*.

Despite their obvious morphological similarity, *Calliaxina kensleyi* and *C. bulimba* were not the two most phylogenetically related of the four species in Robles et al.'s (2020) study. *Calliaxina kensleyi* was sister species to *C. novaebritanniae*, and these two more related to *C. sakaii*, which if true suggests that the vestigial maxilliped 3 exopod has evolved twice. Ovoid plates are visible on the sternite of pleonite 1 (fig. 6c) but absent in *E. bulimba* (fig. 4d).

Dworschak (2005) did not describe the dentition of the lower margin of the merus of the chelipeds of *C. kensleyi*; in the new material there are few proximal denticles (fig. 6e, f). All specimens of *C. bulimba* possess two or three proximal truncated curved teeth and diminishing denticles more distally (fig. 4f). The distomesial face of the propodus of the chelipeds has two rows of submarginal setae in both species. On the

major cheliped of *C. kensleyi*, these setae align in two separate groups of c. 10 and c. 6 setae (figs 6d, 12c); on the minor cheliped, the setae align in two scarcely separate groups of c. 20 and c. 8 setae (fig. 6f; Dworschak, 2005: fig. 3a, c). On both chelipeds of *C. bulimba*, distomesial setae align in two widely separate groups of c. 9 setae each (fig. 4h). The distolateral propodus of the chelipeds is granulated in a concavity at the base of the fingers in some individuals of both species but is absent on others, especially smaller specimens.

The two males identified here as *C. kensleyi* possess a male pleopod 1 typical of several species of *Calliaxina* and *Eucalliaxiopsis*: *C. novaebritanniae*, *C. paradoxa*, *C. punica*, *C. sakaii*, *Eucalliaxiopsis jonesi* (Heard, 1989), *E. mcilhennyi* (Felder and Manning, 1994) and *E. panglaoensis* (all with a broad article 2, appendix interna and curved apex; see fig. 7h, j and earlier papers (Dworschak, 2006, 2014; Felder and Manning, 1994; Heard, 1989; de Saint Laurent and Manning, 1982;). As noted above, the male pleopod 1 of *C. bulimba* differs from all of these, its second article lacking an appendix interna and distal curved apex. The appendix masculina on pleopod 2 of *C. kensleyi* is narrower than that of *C. bulimba*.

Sakai (2017) included *C. kensleyi* in *Eucalliax* although

Figure 6. *Calliaxina kensleyi*. Madagascar, MNHN-IU-2014-10476 (female): a, anterior carapace, eyestalks; b, thoracic sternite 7; c, pleonal sternite 1 (anterior uppermost); d, e, major cheliped (right), mesial, lateral views, with detail of mesial setae on propodus; f, g, minor cheliped (left), mesial, lateral views, with detail of mesial setae on propodus. Scale bars = 1 mm.
Figure 7. *Calliaxina kensleyi*. Saudi Arabia, UF 36699 (male): a, anterior carapace, eyestalks, antennule, antenna; b, maxilliped 3, exopod, basis, ischium; c, telson, uropod; d, major cheliped (left), mesial view; e, major cheliped fingers (left), lateral view; f, minor cheliped (right), mesial view; g, minor cheliped fingers (right), lateral view; h, i, pleopods 1, 2. Madagascar, MNHN-IU-2014-8084 (male): j, pleopod 1. Scale bars = 1 mm.

the species has all the features of *Calliaxina*, however diagnosed. His figure 2A–C, E–G of material from the Red Sea resembles the types from the nearby type locality, Aqaba. His figure 2D of the cheliped of a female from Ambon has a curiously triangular carpus. The location suggests *C. bulimba*, a species he did not mention. He referred to *E. kensleyi* as being from Aqaba and Moreton Bay (*Calliaxina bulimba* is from Moreton Bay, Qld) but listed the type locality as Alona Beach, the Philippines (the type locality of *E. panglaoensis* Dworschak, 2006). The species was not listed by Sakai (2011).

French Polynesia, Moorea Island, NW motus, in channel between

islands and beach, 17.488393° S, 149 91342° W (stn BIZ 148), UF 23954 (female, 5 1 mm)

Australia, Qld, Great Barrier Reef Myrmidon Reef, 18 27° S, 147 38° E, October 1985 lagoon with *"Callianassa"* mounds, 8 m, (M Riddle stn M 10 1), NMV J71677 (female, 11 6 mm), NMV J71678 (male, 8 7 mm), NMV J71669 (2 males, 8 4 mm, 6 ovigerous females, 6 9 10 3 mm, 1 female, 9 4 mm) Myrmidon Reef, 18 27° S, 147 38° E, October 1985 shallow lagoon, 4 m, (M Riddle stn M 10 2), NMV J71670 (2 males, 11 1 mm, 3 ovigerous females, 10 4 mm), outer reef flat, 2 m, (M Riddle stn M 10/3), NMV J71673 (3 males) Rib Reef, 18 48° S, 146 86° S, October 1985 reef flat, 4 m, (M Riddle stn R 10 2), NMV J71671 (4 males, 16 females) reef flat, 8 m, (M Riddle stn R 10 1), NMV J71675 (6 males, smallest 5 5 mm, 4 females) Lizard Island, 50 m W of Loomis beach, 14 6816° S, 145 4515° E, (stn AUST ST 036), UF 16947 (ovigerous female, 9 0 mm) Lord Howe Island, Old Settlement Beach, 31 5° S, 159 1° E (stn LHI 2017 059), AM P100430 (2 males, 11 9 mm, 14 6 mm)

Diagnosis Sternite 7 with transverse groove visible only laterally, anteromedial lobe rounded. Antennule peduncle reaching to midpoint of antenna peduncle article 5 *Maxilliped 3 exopod reaching third to half-way along ischium (juveniles only) or reaching to mid-merus* Major cheliped merus, lower margin with 2 or 3 proximal truncate teeth, propodus distomesial margin with setae aligned in 2 similar groups of c 9 setae each. *Male pleopod 1 article 2 twice as long as wide*, appendix interna prominent

Description of female. Carapace scattered with small shallow depressions, gastric abdominal regions together 4 6 times as long as wide; branchiostegite calcified over dorsal half, separate from wide ventral uncalcified anterior region and narrower triangular uncalcified posterior section, the two separated from each other by squarish calcified plate, posteroventral area without small calcified plates, cervical groove at 0 57 carapace length, scarcely obvious on branchiostegite, cardiac sulcus at 0 73 carapace length, not meeting mid dorsally, extending obliquely anteroventrally to lower limit of calcified branchiostegite

Thoracic sternite 7 1 35 times as long as wide, with well defined median sulcus over posterior third, smooth over medial half, lateral ridge anterior to coxal articulation ending in pit at quarter of width, with 3 posterolateral clusters of long setae

Rostrum broadly triangular, length about 0 25 width of eyestalks Anterolateral carapace lobe half as long as rostrum, with rounded apex, dorsal anterolateral margin oblique in dorsal view as far back as anterodorsal angle of branchiostegite, with c 10 submarginal dorsal setae Pleonites 1 6 lengths relative to cl. 0 42 0 47 0 30 0 30 0 32 : 0 47, pleonite 1 with strong dorsal transverse groove, with pair of oval sternal plates supporting pleopods, each with lateral row of c 20 setae, pleonites 3 5 with lateral tufts of setae, pleonite 6 with 8 lateral rows of setae

Eyestalk 1 85 times as long as wide at base, tapering slightly to cornea, then more rapidly to subacute apices, sometimes with minute mesiodorsal tubercle, cornea round, slightly domed, 0 6 width of maximum eyestalk width Antennular peduncle 2 5 times as long as width of both eyestalks, article 2 3 times as long as wide; article 3 0 6 length of article 2, articles 2 and 3 with ventrolateral row of long setae, continued onto flagellum Antennal peduncle 3 2 times as long as width of both eyestalks, overreaching antennule peduncle by all of article 5,

scaphocerite ovoid, longer than wide, article 4 c 7 times as long as wide; article 5 half as long as article 4 Maxilliped 3 exopod reaching to midpoint of merus, ischium with convex mesial margin, expanding from narrow proximomesial corner; ischium merus 1 8 times as long as greatest width, crista dentata of c 25 even denticles on basis and ischium, carpus dactylus together as long as ischium merus

Chelipeds subequal, major 1 1 length of minor Major cheliped ischium c 2.2 times as long as distal width, lower margin with truncate denticles becoming more distinct distally, merus 2 6 times as long as broad, lower margin with 4 5 truncate proximal denticles, diminishing distally; carpus 1 5 times as wide as upper length, margins carinate; propodus greatest width in middle of palm, as wide as upper palm length, distomesial margin of palm with 2 submarginal groups each of c 8 setae plus nearby granules, distolateral margin of palm with submarginal group of c 10 setae between fingers, fixed finger half as long as upper margin of palm, cutting edge with microdenticles over proximal half, blunt triangular tooth third way along, dactylus as long as fixed finger, twice as long as wide at base, cutting edge concave over proximal half, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers

Minor cheliped ischium c 2 3 times as long as distal width, lower margin with truncate denticles becoming more distinct distally, merus 1 7 times as long as broad, lower margin with 4 5 truncate proximal denticles, diminishing distally, carpus 1 5 times as wide as upper length, margins carinate, propodus palm more evenly wide than major, 1 1 times as wide as upper palm length, distomesial margin of palm with 2 submarginal groups of c 10 and c 12 setae, distolateral margin of palm with submarginal group of c 10 setae, plus 2 smaller groups further from margin between fingers, fixed finger 0 4 times as long as upper margin of palm, mesial cutting edge with microdenticles, blunt proximal tooth, lateral cutting edge microdenticulate defining edge of lateral concavity at base of fixed finger, filled with granules, dactylus overreaching fixed finger, 3 times as long as wide at base, cutting edge curved, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers

Pereopod 2 merus 2 2 times as long as maximum width, dactylus c 3 times as long as upper margin of propodus Pereopod 3 merus twice as long as maximum width, carpus as long as wide, propodus with strongly concave lower margin, twice as long as mid length, dactylus 2 5 times axial length of propodus Pereopod 4 merus 2 3 times as long as maximum width, carpus 2 5 times as long as wide, propodus typically setose, with 2 long distal setae overlapping dactylus

Pleopod 1 article 1 without distal projection beyond article 2, article 2 longer than article 1 Pleopod 2 endopod 2 5 times as long as wide, appendix interna about quarter length of endopod

Uropodal endopod ovoid, anterior margin more convex than posterior margin, widest about third way along, 1 5 times as long as wide, with subdistal facial group of c 8 long setae, exopod 2 4 times as wide as long (length measured from peduncle to anterior point of dorsal plate), distal and posterior margins typically setose, with c 20 blade like setae near end of posterior margin, dorsal plate extending almost over half of

exopod width, posterior margin with spiniform setae Telson 1 7 times as wide as long, broadest at mid length, posterolateral corner more sharply rounded than lateral and posterior margins, posterior margin convex, with lateral lines of long setae, dorsal surface with median row of long setae at anterior quarter

Adult male As in female except as follows Major cheliped propodus, distomesial margin of palm with 2 submarginal groups each of c 8 setae, fixed finger with proximal mesial and lateral granulate ridges, dactylus cutting edge with basal blunt tooth

Minor cheliped propodus, distomesial margin of palm with 2 submarginal groups of c 12 and c 15 setae, distolateral margin of palm with submarginal groups of c 30 and c 15 setae, lateral concavity at base of fixed finger, filled with numerous granules

Pleopod 1 article 1 twice as long as greatest width, article 2 2 3 times as long as wide, appendix interna acute, without hooks, subdistal lobe small, distal curved lobe acute, occupying about third of whole Pleopod 2 endopod 2 3 times as long as wide, appendix masculina attached at c 0 4 of length, 3 5 times as long as distal width, distal margin convex truncate reaching 0 9 length of endopod, with c 20 facial setae near midpoint, c 15 subdistal setae, appendix interna rod like, with hooks, about fifth length of appendix interna

Variation Branchiostegite always divided by oblique longitudinal edge between calcified dorsal region and variously uncalcified ventral region, always with midventral rectangular plate, sometimes with posteroventral tessellated pattern (Sakai, 1999 fig 32e), sometimes more or less calcified, often not calcified Rostrum more acute in smaller specimens (figs 3a, j) Cornea larger in smaller specimens (fig 3j) Maxilliped 3 exopod reaching mid ischium in some small specimens Minor cheliped propodus fixed finger proximal concavity variously granulate

Colour Exoskeleton mostly translucent white, middle of branchiostegites pink (fig 1d, e)

Distribution. Papua New Guinea, Madang, New Britain (type locality) and New Ireland provinces, Indonesia, Sulawesi, Bali, Australia, N Qld, Philippines, Pulawan, French Polynesia Lagoon sediments, to 12 m

Remarks Calliaxina novaebritanniae is unique in the Indo West Pacific in having the exopod of maxilliped 3 reaching to the middle of the merus in adults Small genetic differences were found between the pair from Nago Island (New Britain), one from Madang, one from Palawan, Philippines (NHMW 25366), and one from Indonesia (NHMW 25783) (Robles et al , 2020) Nago Island and Madang, Papua New Guinea, are not far distant, west and east respectively, from the type locality Morphological differences between them, the female from French Polynesia and the large collection from the Great Barrier Reef, Australia, are small The telson and uropod of adults are the same, all have a sulcus on the carapace The maxillipedal 3 exopod reaches to mid merus except in two small specimens where it is shorter than in adults, a phenomenon noted by Liu and Liang (2016) in *C. xishaensis* The rostrum is sharper and the eyestalks more rounded in smaller specimens Article 2 of pleopod 1 of the holotype has two similar distal lobes on its inner margin (one the appendix interna) and an apex strongly curving mesially (de

Saint Laurent and Manning, 1982 fig 6) The appendix interna and second subdistal lobe are less developed in all the Australian males in this collection (fig 9l) A juvenile male from Papua New Guinea has a simple pleopod 1 with three obsolete distal lobes (fig 10h), indicating that this limb metamorphoses with maturity The male pleopod 2 has a broad appendix masculina, with distal and subdistal clusters of long setae, and appendix interna midway on the endopod (fig 10i)

Calliaxina novaebritanniae co occurs in one sample from the Great Barrier Reef with individuals of *C. bulimba* from which it is difficult to distinguish at first glance However, the exopod of maxilliped 3 reaches to the middle of the merus in most *C. novaebritanniae* but is vestigial in all *C. bulimba* The eyestalks of *C. novaebritanniae* are narrower than in *C. bulimba* (almost twice as long as wide vs 0 8 times as long as wide in adults), the antennal peduncles are narrower (antennular peduncle article 2 3 5 times as long as wide vs twice, antennal lpeduncle article 4 6 times as long as wide vs 3 times) The telson of *C. novaebritanniae* is widest at its midpoint whereas in *C. bulimba* it tapers from the base, although the taper is less obvious in juveniles Pereopods of *C. novaebritanniae* are relatively broader than in *C. bulimba* (meri of pereopods 2 and 3, 2 5 and 2 0 times as long as wide vs 2 2 and 2 4 times) The rostrum is more acute in larger *C. novaebritanniae* than in similarly sized *C. bulimba* but is more acute in small specimens of both species

Borradaile (1900) based his description on a single male of total length 37 mm from New Britain (Papua New Guinea) The holotype was illustrated by Borradaile (1900), de Saint Laurent and Manning (1982) and Sakai (1999) Notwithstanding the species' long and complicated synonymy, the material listed here and that from the Philippines and Indonesia (Dworschak, 2018) are the first reported since, De Man (1928a) described and illustrated a specimen he identified as a variety of *C. novaebritanniae*, this was described as *Calliax* (now *Calliaxina*) *punica* by de Saint Laurent and Manning (1982), type locality, Salammbo, Gulf of Tunis De Man (1928b) identified material from the Maldives as *C. novaebritanniae*, this was identified by Sakai (1999) as *Calliax* (now *Eucalliaxiopsis*) *aequimana* (Baker, 1907) but is almost certainly *E. inaequimana* (Dworschak, 2014)

In as far as can be decided from descriptions, *C. novaebritanniae* is indistinguishable from *C. xishaensis* Liu and Liang, 2016 The latter was described from two females from the South China Sea, not far from Palawan, Philippines A specimen from this locality (NHMW 25366) was found to be genetically similar to those from Papua New Guinea (the type locality) and Indonesia, suggesting that the species has a wide distribution *Calliaxina xishaensis* is here synonymised with *C. novaebritanniae. Calliaxina sakaii* is close by in Japan but is morphologically and genetically quite remote (see below and Robles et al , 2020)

Sakai's (1999) designation of the holotype as a lectotype was unnecessary

Calliaxina sakaii de Saint Laurent *in* de Saint Laurent and Le Loeuff, 1979

Figures 11, 12f, g

> *Callianassa (Callichirus) novaebritanniae* Sakai, 1966: 161 168, figs 1 4
> *Callax sakaii* de Saint Laurent *in* de Saint Laurent and Le Loeuff, 1979: 95 de Saint Laurent and Manning, 1982: 212, 222 223, figs 1g, 2c Sakai, 1987: 305 306 Sakai, 2005: 203
> *Paraglypturus sakaii* Sakai, 1999: 124, fig 33d, e
> *Calliaxina sakaii* Ngoc Ho, 2003: 489, 493, 496, fig 20J Sakai, 2011: 502. Sakai, 2018: 739

Material examined Japan, Tomioka, MNHN Th312 (holotype male, 10 mm), MNHN Th313 (female), NMV J59763 (male, 6.7 mm, female, 7 0 mm, ex UI LZ 8894*)

Diagnosis Sternite 7 with complete transverse V-shaped groove, anteromedial lobe acute Antennule peduncle reaching to base of antenna peduncle article 5 Maxilliped 3 exopod reaching third to half way along ischium Major cheliped merus, lower margin with several proximal teeth, propodus distomesial margin with setae aligned in 4 groups of 10, 5, 7 and 4 setae Male pleopod 1 article 2 3 times as long as wide; appendix interna prominent

Remarks Differences between *C. sakaii* and the more widespread *C. novaebritanniae* were confirmed by re examination of the holotype and more recently collected material The male pleopod 1 has a bilobed proximal lobe and pleonal sternite 1 has a pair of oval plates supporting the pleopods, both similar to *C novaebritanniae*. *Calliaxina sakaii* differs from *C. novaebritanniae* in the exopod of maxilliped 3 reaching half the length of the ischium (vs overlapping the merus), a more acute rostrum, fully calcified branchiostegites (vs weakly chitinised over the lower half), having a deep sharp transverse groove on thoracic sternite 7 (vs an obsolete ridge) and the posterior margin of the telson concave (convex) The distomesial margin of the propodus of the major cheliped has four groups of 4 10 submarginal setae, two groups on the minor cheliped (vs two groups on both chelipeds) A lateral concavity at the base of the fixed finger is defined by a lower ridge on both chelipeds

The species was described briefly in footnote number 14 by M. de Saint Laurent alone in de Saint Laurent and Le Loeuff (1979)

Eucalliaxiopsis Sakai, 2011

> *Eucalliaxiopsis* Sakai, 2011: 503 504 Poore et al., 2019: 127 128 (synonymy)

Remarks Eucalliaxiopsis differs from *Calliaxina* in having a strong ridge across the telson, lacking an exopod on maxilliped 3 (with one exception), the appendix masculina overlapping the endopod of pleopod 2, and in the major cheliped of the male usually being more robust, the palm longer and wider, than that of the female. In *Calliaxina*, the telsonic ridge is absent or obsolete, maxilliped 3 always possesses an exopod, the appendix masculina does not reach the apex of the endopod of pleopod 2, and chelipeds of males and females are not differentiated from each other nor scarcely from the minor chelipeds In as much as

can be deduced from published illustrations, the lower margin of the merus of the chelipeds is smooth or with small tubercles at its midpoint in *Eucalliaxiopsis*, whereas this margin bears small proximal truncate teeth in *Calliaxina* The post rostral dorsal area of some species of *Eucalliaxiopsis* (*E. aequimana*, *E. madagassa*) has a broad median longitudinal ridge, seen also in *Eucalliax quadracuta* (Biffar, 1970)

Eucalliaxiopsis includes seven species from the Indo West Pacific, of which three are newly described here, plus three species from the Western Atlantic. *E. cearaensis* (Rodrigues and Manning, 1992) from Brazil, *E. jonesi* from the Bahamas and *E. mcilhennyi* from Florida, USA The species identified as *E* HWI from Hawaii by Robles et al (2020), which is genetically quite separate from six other species, was not available for study

Eucalliaxiopsis panglaoensis, *E. dworschaki* and *E. paradoxa*, the last two being new species described here, differ from the others All possess a transverse telson ridge beset with a row of short spiniform setae, a distally excavate uropodal endopod, a cheliped carpus with two distal spines on the upper margin, two mesiodistal lobes near the apex of the lower lateral margin plus a submarginal distal ridge on the mesial face The carpus is similar to that of *Eucalliax quadracuta*, sole member of its genus The first two of this group were found to be sister taxa by Robles et al (2020) but the others were not monophyletic

Calliaxiopsis Sakai and Turkay, 2014, was synonymised with *Calliaxina* by Poore and Dworschak (2017) *Bakercalliax* Sakai, 2018, *Heardcalliax* Sakai, 2018, and *Manningcalliax* Sakai, 2018, were all differentiated from *Eucalliax*, *Calliaxina* and from each other largely on the basis of the male pleopod 1 but also on the relative sizes of the appendices interna and masculina of pleopod 2 All were synonymised with *Eucalliaxiopsis* by Poore et al (2019), who argued that similar forms of the male pleopod 1 are found in *Eucalliaxiopsis* and *Calliaxina* and that some of the forms used as generic characters by Sakai (2018) are characteristic of juveniles

Key to Indo-West Pacific species of *Eucalliaxiopsis*

1   Telson with row of spiniform setae on transverse ridge, cheliped carpus with 2 short grooves perpendicular to distolateral margin near lower apex, uropodal endopod with apical concavity ...   2

—   Telson without spiniform setae on transverse ridge, cheliped carpus distolateral margin smooth, uropodal endopod ovate   4

2   Cheliped carpus upper margin with proximal hook and subproximal submesial pit, cheliped propodus lateral face with longitudinal ridge extending from near carpus to base of finger, uropodal endopod with 8 short setae between apical clusters, widespread in Indo West Pacific
                 E. dworschaki sp nov

   Cheliped carpus upper margin smooth, cheliped propodus lateral face with longitudinal ridge extending proximally slightly from base of finger; uropodal endopod with 10 11 short setae between apical clusters   3
Figure 11. *Callianassa sakaii* Japan, NMV J59763 (male, 6.7 mm): a, telson, uropod, b, thoracic sternite 7, c, pleonal sternite 1 (anterior uppermost), d, pleopod 1; e, f, major cheliped propodus, dactylus (right), mesial, lateral views, g, h, minor cheliped propodus, dactylus (left), mesial, lateral views. Scale bars = 1 mm.

3   Chelipeds asymmetrical in male, major cheliped propodus longer than wide and longer than in female; distolateral lobe above lower margin of cheliped carpus with acute apex, ridged, oblique; Philippines, Japan
            E. panglaoensis (Dworschak, 2006)

    Chelipeds similar in both sexes, major cheliped palm little longer than wide; distolateral lobe above lower margin of cheliped carpus with rounded apex, longitudinally grooved, perpendicular; NE Australia
                        E. paradoxa sp. nov.

4   Maxilliped 3 with exopod, cheliped merus lower margin with 2 denticles at midpoint, fixed finger with row of equally spaced setae along lateral ridge, telson with rounded posterior margin; female pleopod 2 with free extension beyond rami; Madagascar
            E. madagassa (Sakai and Turkay, 2014)

    Maxilliped 3 without exopod; cheliped merus lower margin smooth, fixed finger with clusters of setae along lateral ridge, telson with truncate or excavate posterior margin; female pleopod 2 without extension beyond rami
                                                                    5

5   Cheliped propodus upper mesial face with row of clusters of setae without associated transverse ridges; major cheliped of male upper margin as long as wide, similar to female, male pleopod 1 article 1 without distal setae, article 2 parallel sided, apically rounded, with marginal setae, without appendix interna; S Australia
                        E. aequimana (Baker, 1907)

    Cheliped propodus upper mesial face with row of short transverse ridges associated with clusters of setae, major cheliped of male upper margin longer than wide, dissimilar to female, male pleopod 1 not as above   6
Figure 12. *Calliaxina* spp. *C. bulimba*: a, major cheliped, mesial. *C. kensleyi*: b, c, major cheliped lateral, mesial. *C. novaebritanniae*: d, major cheliped, mesial; e, minor cheliped, mesial. *C. sakaii*: f, g, minor cheliped mesial, lateral. Thoracic sterna: h, *C. bulimba*; i, *C. kensleyi*; j, *C. novaebritanniae*. Various scales.

6, Antenna peduncle 3 times as long as base of both eyes, most of article 5 exceeding antennule; telsonic ridge sharply elevated, with median notch; uropodal endopod 1.8 times as long as wide; female pleopod 2 without appendix interna; widespread in Indo-West Pacific ....
.... *E. inaequimana* (Dworschak, 2014)

— Antenna peduncle 2.4 times as long as base of both eyes, half of article 5 exceeding antennule; telsonic ridge slightly elevated, complete; uropodal endopod 1.5 times as long as wide; female pleopod 2 with appendix interna; Papua New Guinea .... *E. patio* sp. nov.

Diagnosis Pleonite 1 with pleopods attached to pair of sternal plates. Eyestalk about twice as long as wide. *Antennule peduncle reaching to base of antenna peduncle article 5.* Maxilliped 3

exopod absent. Cheliped carpi distolateral margin square at lower angle, propodi lateral face with oblique longitudinal ridge extending from beyond mid length of palm on to base of finger, upper mesial face with row of clusters of long setae *Male pleopod 1 article 1 without distal setae, article 2 parallel-sided, apically rounded, with marginal setae, without appendix interna.* Female pleopod 2, appendix interna present Uropod endopod ovate. Telson without transverse row of spiniform setae

Description of male. Carapace smooth, with pair of shallow longitudinal groove posterior to rostrum, gastric abdominal regions together 4 3 times as long as wide; branchiostegite calcified, with tessellated pattern of sulci; cervical groove at 0 6 carapace length, scarcely obvious on branchiostegite, cardiac sulcus at 0 76 carapace length, not meeting mid dorsally, extending transversely across half of branchiostegite, with complex branches dorsally

Rostrum blunt or obsolete Anterolateral carapace lobe longer than rostrum, with rounded apex, anteriorly directed, with numerous submarginal dorsal setae

Thoracic sternite 7 1 15 times as long as wide, with well

defined median sulcus over posterior half, lateral groove anterior to coxal articulation poorly defined, oblique, not meeting medially, with 3 posterolateral clusters of long setae. Pleonal sternite 1 with pair of swollen well marked areas anterior to ridge bearing pleopods, without setae. Pleonite 6 lateral margin smooth.

Eyestalks 1.6 times as long as wide at base, tapering around cornea, acute apical tubercle sometimes present, cornea subcircular. Antennular peduncle 2.5 times as long as width of both eyestalks, article 2 2.5 times as long as wide; article 3 0.6 times as long as article 2, articles 2 and 3 with ventrolateral row of long setae, continued onto flagellum. Antennal peduncle 3 times as long as width of both eyestalks, overreaching antennule peduncle by third of article 5, scaphocerite wider than long, subcircular, article 4 c. 5 times as long as wide; article 5 0.6 length of article 4. Maxilliped 3 ischium with slightly convex mesial margin, expanding from narrow proximomesial corner; ischium merus upper margin 1.5 times as long as greatest width, crista dentata of c. 25 small teeth, carpus dactylus together almost as long as ischium merus.

Chelipeds subequal, propodus of major cheliped about 1.2 times that of minor, of similar widths, major dactylus stouter than that of minor. Major cheliped ischium twice as long as distal width, lower margin with short distal tooth, merus 1.8 times as long as broad, lower margin barely convex, unarmed, carpus 1.4 times as wide as upper length, upper margin carinate, distomesial and distolateral margins simple; propodus greatest width proximally, upper palm length 1.1 width, distomesial margin of palm with 2 submarginal groups each of c. 10 setae plus small submarginal bicuspid tooth, distolateral margin of palm with submarginal group of c. 10 setae between fingers plus small submarginal tooth, fixed finger half as long as upper margin of palm, cutting edge with microdenticles over proximal half, obsolete tooth at midpoint, with obsolete lateral ridge extending on to palm, dactylus overreaching fixed finger, 2.2 times as long as width at base, cutting edge sinuous, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers.

Minor cheliped ischium twice as long as distal width, lower margin with distal tooth, merus twice as long as broad, lower margin barely convex, unarmed, carpus 1.2 times as wide as upper length, upper margin carinate, distomesial and distolateral margins simple, propodus palm as wide as upper palm length, upper margin carinate, with blunt distal tooth, distomesial margin of palm with 2 submarginal groups of c. 10 and c. 12 setae, distolateral margin of palm with 2 submarginal groups of c. 8 and 10 setae, fixed finger half as long as upper margin of palm, cutting edge smooth, lateral concavity at base of fixed finger sharply defined by ridge on distal palm, dactylus barely overreaching fixed finger, 3.8 times as long as wide at base, cutting edge sinuous, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers.

Pereopod 2 merus twice as long as maximum width, dactylus 3 times as long as upper margin of propodus. Pereopod 3 merus twice as long as maximum width, carpus 1.6 times as long as wide, propodus with lower margin concave, 1.6 times as long overall as mid length, dactylus half axial length of propodus. Pereopod 4 merus length 2.7 times

maximum width; carpus 2.7 times as long as wide, propodus 1.5 times as long as wide, typically setose, with 1 long distal seta overlapping dactylus.

Pleopod 1 article 1 without distal setae, article 2 parallel sided, apically rounded, 1.8 times as long as article 1, 4 times as long as wide, apex with c. 10 marginal setae, without appendix interna. Pleopod 2 endopod 2.4 times as long as wide, appendix masculina overreaching endopod by about fifth its length, setose along posterior face and distally, lobe like appendix interna near midpoint of appendix masculina. Pleopod 3 with appendix interna submerged in endopod margin.

Uropodal endopod anterior margin convex, posterior margin almost straight, widest about third way along, 1.7 times as long as wide, apex broadly rounded, with 2 groups of long setae at ends of anterior and posterior margins, exopod ovate, all margins continuous, greatest dimension 1.3 times greatest width, with row of blade like distal setae on distal margin, dorsal plate extending beyond half of exopod width, distal margin with spiniform setae. Telson 1.5 times as wide as long, broadest at midpoint, posterolateral corner rounded, posterior margin deeply excavate, with posterolateral cluster of long setae plus short spiniform seta, dorsal surface with sharp transverse ridge at anterior third, notched and with few long setae at midpoint.

Female. Essentially as male except: pleonal sternite 1 with pair of oval plates supporting pleopods, each with longitudinal row of 6–8 single setae emerging from pore. Pleopod 1 peduncle curved, with dense group of plumose setae, article 2 twice as long as article 1.

Distribution. Australia, NSW (as far north as 33° S), Tas., Vic., SA, WA (as far north as 25° S). Intertidal to subtidal sediments.

Remarks. Eucalliaxiopsis aequimana is recognised by the subequal chelipeds that are not sexually dimorphic. In a sample of 14 large specimens, the ratio between the upper propodus margins of major and minor chelipeds ranged from 1.1 to 1.3, with insignificant difference between males and females. The species is notable for the simple setose article 2 of the male pleopod 1, longer than article 1, lacking an appendix interna and acute apex.

The collection from Western Australia includes specimens with carapace lengths ranging 8.9–20.3 mm, most are larger than any from South Australia or Victoria, maximum cl 12.8 mm. They differ most obviously in the near absence of a prominent rostrum (fig. 13j).

Sakai's (2005) synonymy includes references to other species from places outside southern Australia.

Diagnosis. Pleonite 1 with pleopods attached to pair of sternal plates. Eyestalk about twice as long as wide. Antennule peduncle reaching to midpoint of antenna peduncle article 5. Maxilliped 3 exopod absent. *Cheliped carpi distolateral margin with 3 rounded lobes near lower margin separated by submarginal grooves parallel to lower margin, second lobe with slight median depression*, propodi lateral face with horizontal longitudinal ridge extending from near carpus to base of finger, upper mesial face with row of clusters of long setae. Male pleopod 1 article 1 linear, with distal setae; article 2 blade like with subapical medial notch. Female pleopod 2, appendix interna absent. Uropod endopod ovate with excavate apex. Telson with row of spiniform setae on ridge.

Description of holotype male. Carapace length 8 9 mm, smooth, gastric abdominal regions together 4 7 times as long as wide, branchiostegite fully calcified, cervical groove at 0 60 carapace length, scarcely obvious on branchiostegite, cardiac sulcus at 0 77 carapace length, not meeting mid dorsally, extending transversely across third of branchiostegite.

Rostrum acute, tapering to narrow tip, length about 0 4 width of eyestalks. Anterolateral carapace lobe almost as long as rostrum, with rounded apex, anteriorly directed, with numerous submarginal dorsal setae.

Thoracic sternite 7 1 2 times as long as wide, with well defined median sulcus over posterior half, lateral groove anterior to coxal articulation well defined, oblique, meeting medially, with 3 posterolateral clusters of long setae. Pleonal sternite 1 with pair of swollen relatively unchitinised areas anterior to ridge bearing pleopods, without setae. Pleonite 6 with small lateral blunt hook like process at midpoint.

Eyestalks twice as long as wide at base, tapering to cornea and acute apical tubercle, cornea subcircular. Antennular peduncle 3 times as long as width of both eyestalks, article 2 3 5 times as long as wide, article 3 half as long as article 2, articles 2 and 3 with ventrolateral row of long setae, continued onto flagellum. Antennal peduncle 3 4 times as long as width

of both eyestalks, overreaching antennule peduncle by most of article 5, scaphocerite wider than long, with acute apex, article 4 c 5 times as long as wide, article 5 0 65 length of article 4. Maxilliped 3 ischium with slightly convex mesial margin, expanding from narrow proximomesial corner, ischium merus upper margin 1 6 times as long as greatest width, crista dentata of 12 spines, the most proximal reflexed, carpus dactylus together almost as long as ischium merus.

Chelipeds unequal, of similar lengths, propodi of similar widths, major dactylus stouter than that of minor. Major cheliped (left in holotype) ischium twice as long as distal width, lower margin with short spines becoming more distinct distally; merus 1 8 times as long as broad, lower margin mostly straight, unarmed, carpus 1 4 times as wide as upper length, upper margin carinate, with proximal hooked tooth, subproximal mesial pit, distal tooth, distomesial margin with prominent lobe near lower margin, distomesial face with lower submarginal ridge, distolateral margin with rounded notch near upper margin, with 3 rounded lobes near lower margin separated by submarginal grooves parallel to lower margin, second lobe with slight median depression, 2 short setae in lower groove, propodus greatest width in middle of palm, upper palm length equal to greatest width, upper margin carinate, with rounded lobe projecting over dactylus, lower margin carinate, strongly curved mesially, mesial face with short distal uneven setose ridge below upper margin, distomesial margin of palm almost straight, lateral face of palm with prominent ridge running from tubercle near proximal margin on to finger, oblique row of tubercles at proximal end of ridge, each perforated for cluster of setae, fixed finger half length of upper margin of palm, cutting edge with denticles over proximal half, blunt triangular tooth at about midpoint; dactylus as long as fixed finger, twice as long as wide at base, cutting edge with blunt molar, with deflected tip, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers.

Minor cheliped (right in holotype) ischium twice as long as distal width, lower margin with distal spine; merus 1 7 times as long as broad, lower margin mostly straight, unarmed, carpus 1 4 times as wide as upper length, upper margin carinate, with proximal hooked tooth, subproximal mesial pit, distal tooth, distomesial face with lower submarginal ridge, distolateral margin with notch near upper margin, with 3 lobes near lower margin separated by perpendicular submarginal grooves, middle lobe apex rounded, with shallow median groove, 3 short setae in lower groove, propodus greatest width in middle of palm, upper palm length equal to greatest width, as wide distally as proximally, upper margin carinate, overhanging mesial face, with rounded lobe projecting over dactylus, lower margin carinate, strongly curved mesially, distomesial margin of palm almost straight, lateral face of palm with prominent ridge running from tubercle near proximal margin on to finger, oblique row of tubercles at proximal end of ridge, each perforated for cluster of setae, fixed finger 0 7 length of upper margin of palm, width at base half width of palm, cutting edge smooth, dactylus as long as fixed finger, 3 5 times as long as wide at base, cutting edge straight, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers.

Pereopod 2 merus twice as long as maximum width, dactylus c. 2 5 times as long as upper margin of propodus Pereopod 3 merus 2 2 times as long as maximum width, carpus 1 8 times as long as wide, propodus with lower margin concave, 1 5 times as long overall as mid length, dactylus 0 7 times length of axial length of propodus Pereopod 4 merus length 2 7 times maximum width, carpus 2 7 times as long as wide, propodus 1 5 times as long as wide, typically setose, with 1 long distal seta overlapping dactylus

Pleopod 1 article 1 distally setose, article 2 as long as article 1, 4 times as long as wide, with apex curved over subdistal notch, appendix interna freely produced, unarmed Pleopod 2 endopod 2 1 times as long as wide, appendix masculina overreaching endopod by about half its length, setose along posterior face and distally, appendix interna near base of appendix masculina with 5 small hooks Pleopod 3 with appendix interna submerged in endopod margin

Uropodal endopod anterior margin convex, posterior margin convex, widest about third way along, 1 4 times as long as wide, apex excavate, with rows of long setae at ends of anterior and posterior margins, with 11 short setae between in excavation, with subdistal group of facial setae, exopod ovate, anterior margin straight, distal and posterior margins continuous, greatest dimension 2 3 times anterior margin, with row of blade like distal setae on distal margin, c 6 not overlapping with densely setose distal margin, dorsal plate extending almost half of exopod width, distal margin with spiniform setae Telson 1 8 times as wide as long, broadest at midpoint, posterolateral corner squarish, posterior margin sinuous, lateral regions most prominent, with posterolateral cluster of long setae plus 2 short spiniform setae, dorsal surface with sharp transverse ridge at anterior third, with 30 short spiniform setae, few long setae at midpoint

Female Essentially as male except major cheliped palm more tapering than in male, widest proximally Pleonal sternite 1with pair of oval plates supporting pleopods, each with longitudinal row of c 20 setae in clusters of 4 or 5 Pleopod 1 peduncle with mesial setose lobe longer than base Pleopod 2 peduncle with similar lobe directed mesially

Colour Exoskeleton mostly translucent white, upper parts of chelipeds pink (fig 1f, g)

Etymology. For Peter C Dworschak, good friend and colleague, and in recognition of his career devoted to the biology of "thalassinideans"

Distribution. Madagascar, Philippines, Mariana Islands, Papua New Guinea, Indonesia, French Polynesia Intertidal to 8 m

Remarks Eucalliaxiopsis dworschaki is similar to *E. panglaoensis* and *E. paradoxa* (see remarks under *Eucalliaxiopsis* above) *Eucalliaxiopsis dworschaki* differs from both species in possession of a proximal hooked spine and subproximal mesial pit on the upper margin of the carpus of both chelipeds (figs 16g, 25d, e) and a lateral ridge extending almost the entire length of the propodus of both chelipeds (figs 16b, 25b) The palm of the major cheliped of the male is a little longer than wide, while it is 1 25 times as long as wide in

E. panglaoensis The telson is relatively shorter (length width ratio 1 8 vs 1 6) and with a more sinuous posterior margin, and the uropodal endopod is broader (length width ratio 1 4 vs 1 6) Dworschak (2006, pers comm 29 September 2019) reported a small spine on the merus of maxilliped 3 of the allotype of *E. panglaoensis*, and of seven from Sulawesi, here reidentified as *E. dworschaki*. None of the material examined for this study, nor Dworschak's two individuals from Bali, possess this spine *Eucalliaxiopsis paradoxa* is compared below

Dworschak (2006 356, fig 5) remarked on and illustrated two females from Panglao that differed from typical *E. panglaoensis* He noted the hook and pit on the upper margin of the cheliped carpus and the longitudinal ridge on the propodus, characters used here to differentiate *E. dworschaki* The genetic difference from *E. panglaoensis* from the type locality in the Philippines (Robles et al , 2020) and consistent morphology of *E. dworschaki* over a wide geographic range in the Indo West Pacific support recognition of two species Dworschak (2018) listed material of *E. panglaoensis* from Sulawesi and Bali, Indonesia He has now confirmed (pers comm 30 October 2018) that this collection of five males and four females also belongs to *E. dworschaki* The two species occur sympatrically at Panglao and a single individual of *E. dworschaki* was recorded from Guam, not far from the Philippines A large sample of ghost shrimps from the Great Barrier Reef, a sample that included specimens of *Corallianassa* sp (Callichiridae) and *Thomassinia aimsae* Poore, 1997 (Callianideidae), was dominated by *E. paradoxa* but also included one specimen of *E. dworschaki*

There is no genetic difference between the individual from Papua New Guinea and the three sequenced from French Polynesia

Sakai and Turkay (2014) illustrated a single somewhat distorted individual from Papua New Guinea that was identified as *Calliaxina panglaoensis* On the basis of its recorded locality, the specimen is probably *E. dworschaki*

Diagnosis. Pleonite 1 without pair of sternal plates *Eyestalk about twice as long as wide* Antennule peduncle reaching to base of antenna peduncle article 5 Maxilliped 3 exopod absent Cheliped carpi distolateral margin square at lower angle, propodi lateral face without longitudinal ridge, *upper mesial face with row of short transverse ridges associated with more distal clusters of setae.* Male pleopod 1 article 1 linear, with distal setae, article 2 short, oblique, or of single article with narrower distal lobe Female pleopod 2, appendix interna absent Uropod endopod ovate Telson without transverse row of spiniform setae

Colour Exoskeleton mostly translucent white, gastric region, distal propodus of chelipeds with few pink chromatophores (fig 1h, i)

Distribution Australia, Cocos (Keeling) Island (type locality), Qld, Great Barrier Reef; Papua New Guinea, New Ireland, Indonesia, Sulawesi; Philippines, Panglao, French Polynesia Intertidal to 4 m

Remarks Dworschak (2014) distinguished this species, as *Eucalliax inaequimana*, on several features including inequality of the chelipeds in both sexes from *E. aequimana* Usually, only males of *Eucalliaxiopsis* have a significantly larger major cheliped although not all descriptions are clear on this point The same is true of *E. patio* (described and compared below) and both species differ from *E. aequimana* in the ways listed by Dworschak (2014)

Robles et al's (2020) phylogram detected no genetic difference between two individuals from the type locality, two from Papua New Guinea and one from French Polynesia Dworschak (2014) recorded the maximum carapace length as 9.1 mm, the largest in this collection were a male of 7 2 mm and ovigerous female of 6 2 mm His illustrations and description were comprehensive, and many specific details appear on the new material, such as the transverse ridges on the mesial faces of the chelipeds and distal tubercles on the cheliped propodus A broad postrostral obsolete median ridge defined by shallow longitudinal grooves is typical of the new material (fig 18a) but was not mentioned by Dworschak (2014) The feature appears to be more conspicuous in some individuals than others (Dworschak, pers comm. 29 September 2019). The male pleopod 1 is manifest in two forms a long article and shorter second article (fig. 18b, as

figured by Dworschak) and a form where these appear fused (fig 18c)

Poore and Griffin's (1979) specimen of *Callianassa aequimana* from Queensland was reidentified as *E. inaequimana* Sakai's (1999) record of *Calliax aequimana* from the Maldives is almost certainly referable to *E. inaequimana* Sakai (2018) omitted *E. inaequimana* from his revision of Eucalliacinae

Eucalliaxiopsis madagassa (Sakai and Türkay, 2014)

Figure 19

Calliaxiopsis madagassa Sakai and Turkay, 2014 193, fig 13
Calliaxina thomassini Ngoc Ho, 2014 549, fig 2
Calliaxina madagassa Poore and Dworschak, 2017 120, fig 1

Material examined Madagascar. Nosy Bé, W of Hell Ville, 13 41562° S, 48 24648° E (stn MGNW 50), UF 14090 (ovigerous female, 5 8 mm) Toliara (as Tuléar), Thomassin stn 676, MNHN IU 2016 8085 (ovigerous female, 5 8 mm)

Diagnosis. Eyestalk about twice as long as wide Antennule peduncle reaching to midpoint of antenna peduncle article 5 *Maxilliped 3 exopod present* Cheliped carpi distolateral margin square at lower angle, propodi lateral face without longitudinal ridge, upper mesial face with row of clusters of long setae Male pleopod 1 article 1 without distal setae, article 2 parallel sided, apically rounded, with marginal setae, without appendix interna Female pleopod 2, appendix interna absent Uropod endopod ovate Telson without transverse row of spiniform setae

Distribution Madagascar

Remarks Poore and Dworschak (2017) discussed the synonymy and priority of the species names before *Calliaxina* was divided into two by Poore et al (2019) The species is widespread in Madagascar (Ngoc Ho, 2014) and is recognised by rounded posterolateral corners and convex posterior margin of the telson, the continuous dense row of setae on the lateral margin of the fixed finger of the minor cheliped, and the presence (usually) of two or three tubercles at the midpoint of the lower margin of the cheliped merus The ovigerous female differs from that of the male figured by Ngoc Ho (2014) in having a slightly narrower uropodal exopod and in having the chelipeds subequal they are unequal in males of most species of this genus

Eucalliaxiopsis panglaoensis (Dworschak, 2006)

Figure 25g

Eucalliax panglaoensis Dworschak, 2006 349 358, figs 1 4, 6, 7 (not fig 5 *E dworschaki* sp nov) Osawa and Fujita, 2016 40 41, fig 3c Dworschak, 2018 17, fig 1 (partim)
Calliaxina panglaoensis Sakai, 2011 501
Eucalliaxiopsis panglaoensis Poore et al, 2019 125, 127, 146, fig 19m Robles et al, 2020

Material examined Paratypes Philippines, Panglao Island, 09° 38 3' S, 123° 49 6' E, MNHN Th1503 (female, 7 1 mm), MNHN Th1504 (male, 4 3 mm)

Diagnosis. Pleonite 1 with pleopods attached to pair of sternal plates. Eyestalk about twice as long as wide Antennule peduncle

reaching to midpoint of antenna peduncle article 5 Maxilliped 3 exopod absent *Cheliped carpi distolateral margin with 3 acute teeth near lower margin separated by wide grooves parallel to lower margin, second tooth with acute ridge,* propodi lateral face without longitudinal ridge, upper mesial face with row of clusters of long setae Male pleopod 1 article 1 linear, with distal setae; article 2 blade like with subapical medial notch Female pleopod 2, appendix interna absent Uropod endopod ovate with excavate apex Telson with row of spiniform setae on ridge

Distribution Philippines, Panglao, Japan, Ryukus, Miyako Group Sandy beaches, intertidal to 4 m

Remarks *Eucalliaxiopsis panglaoensis* differs from *E. paradoxa* and *E. dworschaki* (see remarks under *Eucalliaxiopsis* above and these two species) in armature of the cheliped The marginal teeth at the lower distal angle of the carpus are more widely spaced, and the second more sharply ridged than in the other two The longitudinal lateral ridge on the propodus is shorter than in *E. dworschaki* but more prominent than in *E. paradoxa* (fig 25g, Dworschak, 2006)

The record of this species, rather than *E. dworschaki*, from Japan is based on the illustration of the cheliped with a short lateral propodal ridge (Osawa and Fujita, 2016 fig 3c)

Eucalliaxiopsis paradoxa sp. nov.

Paratype, NMV J71684 (female, 10.4 mm): r, minor cheliped carpus, distolateral margin. Scale bars = 1 mm.

rostrum, with rounded apex, anteriorly directed, with numerous submarginal dorsal setae

Thoracic sternite 7 1 3 times as long as wide, with well defined median sulcus over posterior half, lateral groove anterior to coxal articulation shallow, oblique, meeting medially, with 7 posterolateral clusters of 2 or 3 long setae Pleonal sternite 1with pair of swollen relatively unchitinised areas anterior to ridge bearing pleopods Pleonite 6 with small lateral blunt hook like process at midpoint

Eyestalk 2 2 times as long as wide at base, tapering to cornea and acute apical lobe, cornea subcircular, apical lobe extended dorsally Antennular peduncle 3 times as long as width of both eyestalks, article 2 3 5 times as long as wide, article 3 half as long as article 2, articles 2 and 3 with ventrolateral row of long setae, continued onto flagellum Antennal peduncle 3 4 times as long as width of both eyestalks, overreaching antennule peduncle by half of article 5, scaphocerite wider than long, with acute apex, article 4 c 5 times as long as wide, article 5 0 6 length of article 4 Maxilliped 3 ischium with slightly convex mesial margin, expanding from narrow proximomesial corner, ischium merus upper margin 1 7 times as long as greatest width, crista dentata of 12 spines, the most proximal reflexed, carpus dactylus together almost as long as ischium merus

Chelipeds unequal, major propodus 1 2 times as long as that of minor, both of similar widths, major dactylus stouter than that of minor Major cheliped (right in holotype) ischium twice as long as distal width, lower margin with short spines becoming more distinct distally, merus twice as long as broad, lower margin mostly straight, unarmed, upper margin with distal tooth, carpus 1 2 times as wide as upper length, upper margin carinate, unarmed except for distal tooth, distomesial margin with prominent lobe near lower margin, distolateral margin with acute tooth near upper margin, with 3 acute teeth near lower margin separated by submarginal oblique grooves, second tooth with prominent rounded ridge, 3 short setae in lower groove, propodus widest proximally, tapering, upper palm length barely exceeding greatest width, upper margin straight, carinate, with rounded lobe not projecting over dactylus, lower margin carinate, strongly curved mesially, mesial face with short distal uneven setose ridge below upper margin, distomesial margin of palm almost straight, lateral face of palm with short horizontal ridge, about fifth length of palm, extending on to finger, 4 rimmed tubercles near proximal margin, 1 at midpoint of palm, 1 near lower margin, each perforated for cluster of setae, fixed finger half length of upper margin of palm, cutting edge with denticles over proximal half, blunt triangular tooth near midpoint, dactylus as long as fixed finger, twice as long as wide at base, cutting edge with blunt proximal molar, with straight tip, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers

Minor cheliped (left in holotype) ischium twice as long as distal width, lower margin with distal spines, merus twice as long as broad, lower margin mostly straight, unarmed, carpus 1 2 times as wide as upper length, upper margin carinate, unarmed except for distal tooth, distomesial face with lower

submarginal ridge, distolateral margin with acute tooth near upper margin, with 3 teeth near lower margin separated by submarginal oblique grooves, second tooth acute with prominent rounded ridge, 2 short setae in lower groove, propodus greatest width proximally, tapering, upper palm length equal to greatest width, palm tapering, upper margin carinate, overhanging mesial face, with rounded lobe projecting over dactylus, lower margin carinate, strongly curved mesially, mesial face with 4 blunt teeth at associated with upper row of clusters of setae, distomesial margin of palm almost straight, lateral face of palm with prominent ridge running from two thirds length of palm to middle of finger, 5 rimmed tubercles near proximal margin of which 1 near midpoint of palm is more distal, each perforated for cluster of setae, fixed finger 0 7 length of upper margin of palm, width at base half width of palm, cutting edge smooth, dactylus as long as fixed finger, 3 2 times as long as wide at base, cutting edge straight, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers

Pereopod 2 merus twice as long as maximum width, dactylus c 3 times as long as upper margin of propodus Pereopod 3 merus twice as long as maximum width, carpus 1 8 times as long as wide, propodus with lower margin concave, twice as long overall as mid length, dactylus 0 7 times length of axial length of propodus Pereopod 4 merus length 2 2 times maximum width, carpus 2 5 times as long as wide, propodus as long as wide, typically setose, with 1 long distal seta overlapping dactylus

Pleopod 1 article 1 distally setose, article 2 as long as article 1, 4 times as long as wide, with apex curved, appendix interna lobe like, not produced, unarmed Pleopod 2 endopod twice as long as wide, appendix masculina overreaching endopod by about third its length, triangular in cross section, setose along posterior face and distally, appendix interna near base of appendix masculina without hooks

Uropodal endopod anterior margin convex, posterior margin convex, widest about third way along, 1 4 times as long as wide, apex excavate, with rows of long setae at ends of anterior and posterior margins, with 8 short setae between in excavation, with subdistal group of facial setae, exopod ovate, anterior margin straight, distal and posterior margins continuous, greatest dimension 2 2 times anterior margin, with row of blade like distal setae on distal margin, c 6 not overlapping with densely setose distal margin, dorsal plate extending almost half of exopod width, distal margin with spiniform setae Telson 1.6 times as wide as long, broadest at midpoint, posterolateral corner rounded, posterior margin sinuous, lateral regions most prominent, with posterolateral cluster of long setae plus 2 short spiniform setae, dorsal surface with sharp transverse ridge at anterior third, with 36 short spiniform setae, few long setae at midpoint

Female Essentially as male except major cheliped palm tapering, upper length 0 9 greatest width, upper margin convex, depressed distally, lateral ridge longer than in male, fixed finger broader than in male, crenellate proximal and distal to tooth Pleonal sternite 1with pair of oval plates supporting pleopods, each with longitudinal row of setae Pleopod 1 peduncle with

mesial setose lobe longer than base Pleopod 2 peduncle with similar mesial setose lobe; endopod without appendix interna

Etymology. Paradoxa (Latin), reflecting the subtle differences from *E. panglaoensis* and co occurring *E. dworschaki*, and a tribute to the collector's name, Martin Riddle

Distribution. Australia, Qld, central Great Barrier Reef (18° S) Subtidal coral reef lagoons

Remarks Eucalliaxiopsis paradoxa shares several features with *E. panglaoensis* and *E. dworschaki* (see remarks under *Eucalliaxiopsis* above) The new species differs from these two in having eight short setae in the uropodal endopod excavation (fig 21e, 11 in the other species), a short longitudinal ridge at the base of the finger on the lateral face of the chelipeds, the propodus of the male cheliped tapering (more rectangular in the others), and the middle distolateral cheliped carpal tooth being oblique and sharply ridged (figs 20g, i, 21m, o, r, 25h) In *E. dworschaki*, the ridge on the palm extends almost its entire length, and the middle carpal lobe is perpendicular and with a median groove Besides having fewer short setae at the end of the uropodal endopod, *Eucalliaxiopsis paradoxa* differs from *E. panglaoensis* in the upper margin of the male major cheliped palm being as long as wide (vs 1 3 times as long as palm width), the palm of the female major cheliped being relatively longer (1 1 vs 0 9 times as long as greatest width), the uropodal endopod being more tapered (more oval in *E. panglaoensis*) and the sinuous posterior margin of the telson (vs straight)

Figures 22 24

Eucalliaxiopsis PNG 1153C Robles et al , 2020

Material examined Holotype Papua New Guinea, New Ireland Province, Patio Island, 02° 36 2' S, 150° 31 6' E, 6 8 m, coral rubble (KAVIENG 2014 stn KB38), MNHN IU 2014 2536* (female, cl 4 6 mm)
Paratype Collected with holotype (MNHN IU 2014 2539 (male, cl 4 3 mm, with male and female bopyrid isopods under left branchiostegite)

Diagnosis. Pleonite 1 without pair of sternal plates Eyestalk 1.5 times as long as wide Antennule peduncle reaching to midpoint of antenna peduncle article 5 Maxilliped 3 exopod absent Cheliped carpi distolateral margin square at lower angle, propodi lateral face without longitudinal ridge, upper mesial face with row of short transverse ridges associated with more distal clusters of setae Male pleopod 1 of single article with narrower distal lobe Female pleopod 2, appendix interna present Uropod endopod ovate Telson without transverse row of spiniform setae

Description of holotype female. Carapace length 4 6 mm, smooth, gastric abdominal regions together 4 2 times as long as wide, branchiostegite fully calcified, cervical groove at 0 67 carapace length, scarcely obvious on branchiostegite, cardiac sulcus at 0 83 carapace length, not meeting mid dorsally, extending transversely across two thirds of branchiostegite

Rostrum broadly rounded triangular, length about 0 2 width of eyestalks Anterolateral carapace lobe as long as rostrum, with rounded apex, depressed anteriorly, with c 5 submarginal dorsal setae Pleonites 1 6 lengths relative to cl 0 46 · 0 67 0 45 0 33 , 0 41 0 51; pleonite 1 with strong dorsal transverse groove, without pair of sternal plates, pleonites 3 5 with lateral tufts of setae, pleonite 6 with 8 lateral rows of setae

Thoracic sternite 7 1 2 times as long as wide, with well defined median sulcus over posterior half, smooth over medial half, lateral ridge anterior to coxal articulation crossing pit at quarter of width, meeting medially, with 3 posterolateral clusters of long setae

Eyestalk 1 7 times as long as wide at base, swollen laterally, tapering to cornea and acute apical tubercle; cornea wider than long, depressed anteriorly Antennular peduncle twice as long as width of both eyestalks, article 2 twice as long as wide, article 3 as long as article 2, articles 2 and 3 with ventrolateral row of long setae, continued onto flagellum Antennal peduncle 2 4 times as long as width of both eyestalks, overreaching antennule peduncle by half of article 5, scaphocerite ovoid, longer than wide, article 4 c 5 times as long as wide, article 5 0 8 length of article 4 Maxilliped 3 ischium with slightly convex mesial margin, expanding from narrow proximomesial corner, ischium merus upper margin twice as long as greatest width, crista dentata of 6 spines, the 2 most proximal largest, carpus dactylus together almost as long as ischium merus

Chelipeds unequal, major carpus propodus upper margin 1.1 length of minor, propodus 1 2 times as wide as minor Major cheliped (left in holotype) ischium twice as long as distal width, lower margin with needle like spines becoming more distinct distally, merus 1 7 times as long as broad, lower margin convex, unarmed, carpus 1 2 times as wide as upper length, margins carinate, propodus greatest width in middle of palm, upper palm length 1 15 times greatest width, distomesial margin of palm with submarginal group of 2 setae, small tubercle, distolateral margin of palm with submarginal group of c 6 setae between fingers, fixed finger 0 4 length of upper margin of palm, cutting edge with microdenticles over proximal half, blunt triangular tooth at about midpoint, dactylus as long as fixed finger, twice as long as wide at base, cutting edge with deflected tip, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers, 3 short transverse ridges associated with setae on submesial upper margin

Minor cheliped (right in holotype) ischium c 2 3 times as long as distal width, lower margin with needle like spines becoming more distinct distally; merus 1 7 times as long as broad, lower margin convex, unarmed, carpus 1 2 times as wide as upper length, margins carinate; propodus palm more tapering than major, 0 95 times as wide as upper palm length, distomesial margin of palm with submarginal group of 4 12 setae, distolateral margin of palm with submarginal group of c 4 setae; fixed finger half length of upper margin of palm, mesial cutting edge straight, smooth, cutting edge straight, fixed finger with smooth lateral ridge defining edge of lateral concavity at base of fixed finger, without granules, dactylus as long as fixed finger, 3 times as long as wide at base, cutting edge straight, submarginal tufts of long setae on upper and lower mesial
Figure 22 *Eucalliaxiopsis patio* sp nov. Figure 23 *Eucalliaxiopsis patio* sp. nov. Holotype, MNHN IU 2013 2536 (female, 4 1 mm) a, major cheliped (left), mesial; b, major cheliped (left), distal propodus, dactylus, lateral; c, minor cheliped (right), mesial view, d, minor cheliped (right), distal propodus, dactylus, lateral; e h, pereopods 2 5, i, j, pleopods 1, 2 Scale bars 1 mm

margins of carpus and propodus, opposing mesial margins of fingers; 2 short transverse ridges associated with setae on submesial upper margin, more prominent distally

Pereopod 2 merus 1.8 times as long as maximum width, dactylus c 3 times as long as upper margin of propodus Pereopod 3 merus 2 2 times as long as maximum width, carpus 1.8 times as long as wide, propodus with lower margin almost straight, 1.8 times as long as mid length; dactylus half as long as axial length of propodus Pereopod 4 merus twice as long as maximum width; carpus 3 times as long as wide, propodus typically setose, with distal spiniform setae among setose margin, with 2 long distal setae overlapping dactylus

Pleopod 1 article 1 without distal projection beyond article 2; article 2 longer than article 1. Pleopod 2 endopod 3 times as long as wide, appendix interna at midpoint of endopod

Uropodal endopod ovoid, anterior margin more convex

Figure 24. *Eucalliaxiopsis patio* sp. nov. Paratype, MNHN IU 2013 2539 (male, 4 6 mm). a, b, anterior carapace, eyestalks, dorsal and lateral views; c, major cheliped (right), mesial, d, major cheliped (right), propodus, dactylus, upper, e, minor cheliped (left), mesial view, f, minor cheliped (left), propodus, dactylus, upper, g, h, pleopods 1, 2 Scale bars   1 mm

than posterior margin, widest about third way along, 1.5 times as long as wide, with subdistal group of facial setae, exopod ovate, anterior margin straight, distal and posterior margins continuous, greatest dimension 2.2 times anterior margin, with row of blade like distal setae on distal margin, c. 6 not overlapping with densely setose distal margin, dorsal plate extending almost half of exopod width, distal margin with spiniform setae Telson 1 6 times as wide as long, broadest over anterior half, posterolateral corner evenly rounded to posterior margin; posterior margin barely convex, with posterolateral clusters of long setae, dorsal surface with obscure rounded transverse ridge at anterior third, without median notch

Paratype male Carapace length 4.3 mm. Eyestalks 1 5 times as long as wide at base, swollen laterally, tapering to cornea and acute apical tubercle, cornea wider than long, depressed anteriorly Postrostral dorsal area with pair of shallow pits

Chelipeds unequal, major carpus propodus upper margin 1.1 length of minor, propodus 1 3 times as wide as minor. Major cheliped (right) ischium twice as long as distal width,

lower margin with denticles, 1 distal spine, merus 1.7 times as long as broad, lower margin convex, unarmed; carpus 1 4 times as wide as upper length, margins carinate, propodus greatest width in middle of palm, upper palm length 1 15 times greatest width, distomesial margin of palm with submarginal group of 2 setae plus tubercle; fixed finger 0 35 length of upper margin of palm, cutting edge with microdenticles over proximal half, blunt triangular tooth near midpoint; dactylus as long as fixed finger, twice as long as wide at base, cutting edge irregular, with deflected tip, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers, 4 short transverse ridges associated with setae on submesial upper margin

Minor cheliped (left) ischium c 2 3 times as long as distal width, lower margin with denticles, 1 distal spine, merus 1 8 times as long as broad, lower margin convex, unarmed, carpus 1.1 times as wide as upper length, margins carinate, propodus palm more tapering than major, 0 95 times as wide as upper palm length, distomesial margin of palm with 2 submarginal
Figure 25. *Eucalliaxiopsis* spp. *E. aequimana*: a, b, major cheliped, mesial. *E. dworschaki*, Papua New Guinea, MNHN-IU-2013-10003: c, d, major cheliped lateral, upper margin. *E. dworschaki*, Philippines, NHMW 20923: e, f, major cheliped carpus lower lateral angle, upper margin. *E. panglaoensis*, NHMW 20922: g, minor cheliped, lateral. *E. inaequimana*: h, major cheliped, mesial. *E. paradoxa*: h, i, major cheliped lateral, mesial. Photos e–g: P.C. Dworschak. Various scales.

groups of 2 3 setae, fixed finger 0.4 length of upper margin of palm, mesial cutting edge straight, smooth, dactylus as long as fixed finger, 2 8 times as long as wide at base, cutting edge straight, submarginal tufts of long setae on upper and lower mesial margins of carpus and propodus, opposing mesial margins of fingers, 3 short transverse ridges associated with setae on submesial upper margin, more prominent distally

Pleopod 1 articles indistinguishable; article 1 with 1 short, 4 long distal setae, article 2 a short triangle, half as wide as article 1 Pleopod 2 endopod 2 7 times as long as wide, appendix masculina attached at mid length, 5 times as long as width, distal margin rounded, exceeding endopod by fifth of its length, with c 9 facial setae near midpoint, c 14 subdistal setae; appendix interna rod like, about 0 4 length of appendix interna

Etymology From Patio Island, Papua New Guinea, the type locality (noun in apposition)

Distribution Papua New Guinea Coral rubble, 6 8 m

Remarks The holotype was sister taxon to five individuals of *E. inaequimana* on the phylogenetic tree of Robles et al (2020) Both species have submarginal mesial transverse ridges on the cheliped propodi from which tufts of long setae emerge, in other species of *Eucalliaxiopsis* the same tufts are not supported in this way. The male pleopod 1 of both species has a simple second article, free or fused, a form seen too in *E. madagassa* (see Poore and Dworschak, 2017 fig 1C, D), *Eucalliax quadracuta* and *Calliaxina bulimba* (see above) The typical article 2 of species of *Eucalliaxiopsis* is flattened with a distal oblique notch *Eucalliaxiopsis patio* differs from *E. inaequimana* in shorter, more swollen eyestalks (1 5 vs 1 8 times as long as wide), slightly shorter rostrum (quarter vs fifth length of eyestalk), shorter antenna peduncle (2 4 vs 3 0 times as long as base of both eyes), more compact antennular and antennal peduncular articles, the telsonic ridge being only slightly elevated and complete (vs clearly elevated, with median notch), and a broader uropodal endopod (1 5 vs 1 8 times as long as wide) The appendix interna on the female pleopod 2 is present while it is absent in *E. inaequimana* It is possible that this difference may be related to the female's small size; Dworschak (2006) noted that the smallest female of *E. panglaoensis* possessed an appendix interna while larger ones did not Two individuals were collected from the type locality, with carapace lengths of 4 3 and 4 6 mm The largest known specimen of *E. inaequimana* has a carapace length of 9 1 mm

Identification of these specimens using Sakai's (2011) key to species of *Calliaxina* leads to *C. aequimana*, a southern Australian species This species, now *Eucalliaxiopsis aequimana*, lacks mesial ridges on the chelipeds and has a female like male pleopod 1

Pseudocalliax Sakai, 2011

Pseudocalliax Sakai, 2011 505 506 Sakai, 2018 744. Poore et al , 2019 128, 146, figs 18a, k, 19e, r

Remarks The type and only species was placed in Eucalliacinae, now Eucalliacidae, as a species of *Calliax*, by Sakai (2005) Sakai (2011) erected the new genus *Pseudocalliax* for it in the same subfamily. No molecular sequences were available to Robles et al (2020) to challenge this placement that has good morphological support (Poore et al , 2019) The genus shares with the three species of *Calliax* the characteristic short fixed finger on the minor cheliped

Pseudocalliax tooradin (**Poore and Griffin, 1979**)

Material examined Australia, Vic , Western Port, Crib Point, 38° 20 23' S, 145° 13 38' E, 5 m (CPBS stn 11N), NMV J301 (holotype female, 5 2 mm), NMV J302 (2 paratype females), 38° 21.17' S, 145° 13 15' E, 2 m (CPBS stn 000), NMV J303 (paratype male, 6 5 mm) San Remo, channel edge, E. of No 7 beacon, 38° 32' S, 145° 23' E (MRG Transect 1), NMV J59760 (male, 5 1 mm); N from 200 m E of Back Beach Rd to channel edge, 38° 32' S, 145° 23' E (MRG transect 2), NMV J59761 (2 males, 4 2, 6 0 mm) Swan Bay, Edwards Point, 38° 13 3' S, 144° 41 4' E, 2 m, NMV J16722 (juvenile, 1 5 mm)

Distribution. Australia, Vic , entrances of Western Port and Port Phillip Bay Subtidal, c 2 m

Remarks Poore and Griffin (1979) provided only a short description and simple figures Here, the antennae, chelipeds, terminal articles of pereopods 3 and 4, male pleopods, telson and uropod are figured The species is notable for the setose thoracic sternite 7 and ventroposterior surface of the coxa ischium of pereopod 5, a feature diagnostic for the genus (fig 26b) The antenna bears a free scaphocerite, longer than broad, with a rounded apex (fig 26a) The exopod of maxilliped 3 typically reaches the middle of the merus but is shorter on smaller individuals While the fixed finger of the minor cheliped is shorter than the dactylus in most individuals it is almost as long in one male The propodus of pereopod 3 is suboval, little longer along its upper margin than its greatest width, and densely setose on its lateral face The propodus of pereopod 4 is elongate oval, 1 5 times as long along its upper margin than its greatest width, with a distal long spiniform setae on the lower margin, and densely setose on its lateral face The male pleopod 1, overlooked by Poore and Griffin (1979), has a shorter second article with an apical notch (fig 26g) The peduncle of the male pleopod 2 is longer than broad, the appendix interna is short and lacks hooks, no appendix masculina is present (fig 26h) The appendix interna on the endopod of pleopod 3 is triangular, longer than broad, emerging by about half its length (fig 26j) The uropodal endopod is oval, 1 8 times as long as wide, with marginal setae, the exopod is 1 6 times as long as wide, with short spiniform setae along its apical margin, with a well defined dorsal plate with c 6 short spiniform setae and many longer setae (fig 26f) A dorsal oval, cardiac prominence and cardiac sulcus are all absent, all known material is in NMV (cf contradictory statements and figures in Sakai, 1999, and Sakai, 2011)
Figure 26. *Pseudocalliax tooradin* Poore and Griffin, 1979. Australia, Vic., Western Port, NMV J303 (paratype male, 6.5 mm): a, anterior carapace, eyestalks, antennule, antenna; b, posterior carapace, pleonite 1, coxa 4, thoracic sternite 7, coxa basis 5, pleopod 1; c, maxilliped 3, with crista dentata; d, e, propodus, dactylus, pereopods 3, 4; f, telson, uropod; g, pleopod 1; h, pleopod 2; j, appendix interna, pleopod 3. NMV J301 (holotype female, 5.2 mm) i, pleopod 2. Scale bars: 1 mm.

Abstract

Luckett, W.P., Hong Luckett, N., and Harper, T. 2021. Initiation and early development of the postcanine deciduous dentition in the dasyurid marsupial *Dasyurus viverrinus*. *Memoirs of Museum Victoria* 80: 43–58

There has been disagreement for more than 100 years concerning the presence or absence of deciduous and successional third premolars in the dentition of the Australian dasyurid marsupial *Dasyurus viverrinus* as well as in other species of the genus *Dasyurus*. Most authors during the 19th and 20th centuries have considered the missing premolar in *Dasyurus* to be the third premolar family in both jaws, in part because of the reduction in size of the third deciduous premolar in many other genera of dasyurids. While other authors, found "the deciduous premolar to be constantly present in the young mammary foetus as a small and precociously calcified vestigial tooth". However, the fate of this deciduous tooth, and its possible successor in later developmental stages, was never described, and the vestigial dp3 and its possible successor were assumed to undergo absorption during foetal life. With access to later developmental stages of *Dasyurus viverrinus*, via the extensive collections of Professor J.P. Hill, we present new evidence for the later development of dP3 and P3 in both jaws, the probable eruption of the successional P3 in both jaws and evidence that dP2 is the missing tooth in both jaws of this dasyurid species

Keywords

Dasyurus, deciduous dentition, dental development, dental homologies, pouch young

Introduction

During the years 1895–1905, when he was a Demonstrator of Biology at the University of Sydney, Australia, Professor James P. Hill collected a large sample of juveniles of the dasyurid marsupial *Dasyurus viverrinus*, ranging from newborn young to individuals about four months old. The species was still relatively common in New South Wales at the time and the animals lived relatively well in captivity. Many of these captive bred dasyurids produced the dated pouch young that are the subject of this paper. Although Hill and colleagues published several papers on the early development, placentation and reproduction in general of *Dasyurus*, only one paper dealt specifically with the development of the pouch young

An extensive series on the development of the growth stages in the pouch young of *Dasyurus viverrinus* was examined in a monograph by Hill and Osman Hill (1955). The authors presented 16 figures of the pouch young, and they described in detail the external morphology of the developing young in a series of stages labelled A to P. These ranged from unattached newborn young outside and inside the pouch, measuring 5.5

6.0 mm greatest length (GL) and 2.5 mm head length (HL; stage A), up to adolescent young that were four months old (stage P). These oldest young were freely moving about outside the pouch and measured about 60 mm HL. However, no description or figures of the microscopic anatomy of the developing teeth were presented. Unfortunately, Hill passed away in 1954 during the preparation of their manuscript. We suspect that Hill would have published a detailed description of the developing dentition if he had lived longer. After his death, at least a portion of his collections of mammalian embryos and young animals was donated to the Hubrecht Laboratory of Comparative Embryology, Utrecht, Netherlands. These included a series of histological sections of some of the *Dasyurus viverrinus* pouch young described by Hill and Osman Hill (1955) and some older juveniles preserved as alcohol specimens. A few of the alcohol specimens from Hill's collection were borrowed and sectioned by Professor Louis Bolk, University of Amsterdam, Netherlands, and then returned to the Hubrecht Laboratory of Comparative Embryology

Materials and methods

It is rare to be able to histologically examine closely related stages of early developing pouch young for any marsupial, and we were able to study three unattached intrauterine embryos and 22 early developing stages of pouch young attached to the nipple for *Dasyurus viverrinus* from the Hill collection The pouch young examined range in age from about 30 hours old, measuring about 6 mm GL, to 40 41 days old, and measuring about 29 mm GL Given that this species appears to be a useful model for the developmental relationships of the dentition in the extinct dasyuromorphian *Thylacinus cynocephalus* (see Luckett et al , 2019), along with other marsupicarnivore taxa, we present this overview of early dental development in *Dasyurus viverrinus* These studies were carried out over a period of several years at the Hubrecht Laboratory of Comparative Embryology before the embryological collections were transferred to their present home in the Museum fur Naturkunde, Berlin, Germany

It should be noted that *Dasyurus viverrinus* is probably extinct on mainland Australia, with a last sighting on January 1963 in the suburbs of Sydney (Dickman et al , 2001) The species persists in Tasmania , although it is vulnerable there for several reasons, including climate change and disease, among other possibilities (Fancourt, 2016)

A brief overview of our findings on dental development in *Dasyurus* was presented previously (Luckett, 1989, 1993) We have made new drawings of four of the developing pouch young (fig 1) examined by us from the Hill collection, ranging from an early attaching pouch young of about 30 hours old to an embryo of about 41 days old, measuring about 29 mm GL and 18 mm HL. Most genera of dasyurids, peramelids and didelphids have three premolars in both jaws of adults This is presumably the primitive condition for marsupials (Cifelli et al , 1996) Emphasis in our study is given to the evidence for loss of dP2 in this dasyurid with two premolars, and the accelerated development of dP3 and P3, when compared with these features in dasyurids with three premolars A summary of the major features of early development for the deciduous and successional dentition in marsupials is presented in fig 2

Results

Early development of the dental lamina

Hill and Osman Hill (1955) noted that the earliest date of gestation was 16 days in their sample of *Dasyurus viverrinus* embryos The earliest evidence of a dental lamina that we found was detected in the maxilla of three intrauterine embryonic stages of 5 5 6 mm GL In the youngest of these embryos, the dental lamina was detected bilaterally in the upper jaw as a localised thickening of the oral epithelium that was associated with a very early differentiation of bone (or prebone) in the distal portion of the developing maxilla In contrast, the dental lamina and developing bone were not yet detected in the premaxillary region of the upper jaw The more mature intrauterine young showed dental lamina thickenings in both the premaxilla and maxilla regions of the upper jaw The dental lamina was not yet evident in the lower jaw of the youngest intrauterine embryo As explained by Hill and Osman Hill (1955), the newborn young of *Dasyurus viverrinus* are able to find their way to the mother's pouch, unaided by the mother and helped by their own well developed forelimbs that have very sharp deciduous claws

In the youngest pouch young attached to the mother's nipple, examined at about 30 hours old and measuring 6 mm GL, a continuous dental lamina was present bilaterally in both the upper and lower jaws This specimen was illustrated as fig 5 by Hill and Osman Hill (1955) and we have redrawn this important specimen in our fig 1a The HL of this pouch young was 3 25 mm It should be noted here that all of our measurements from the Hill collection are taken from specimens that had been placed in spirit fixation by Hill In the upper jaw, three early bud thickenings are evident on the dental lamina (see fig 2a for the relations between the dental lamina and an early bud) The most rostral of these is associated with the premaxillary ossification, the next is adjacent to the rostral end of the developing maxillary bone, and the distal bud occurs at the caudal end of the dental lamina and is associated with the distal extent of the maxillary ossification Based on their bony relationships and comparison with later ontogenetic stages, these tooth buds can be identified as dI2 or dI3 anteriorly, dC and dP3, respectively The dP3 bud lies beneath the level of the anterior half of the eye An overview of the major features of dental development for the postcanine dentition in the upper and lower jaws is summarised in Tables 1 and 2

The bud for the early developing incisors in the upper jaw does not occur at the rostral most extent of the premaxilla, instead, it is positioned somewhat more distolateral It is unclear whether this developing tooth germ is dI2 or dI3 at this early stage The late or retarded development of dI1 in the upper jaw of dasyurids, peramelids and didelphids was noted by Thomas (1887) Later, Guiler and Heddle (1973) suggested that the late development and eruption of dI1 helped the continued suckling of the young In the lower jaw, a large early bud is evident at the rostral extent of the dentary ossification Two small bud like thickenings occur distal to the rostral early bud (presumably di1), but these are not as distinct as the di1 It should be noted here that adult dasyurids possess four upper and three lower incisors, in contrast to the presumably primitive condition in ancestral marsupials and didelphids, which possessed five upper and four lower incisors It is unclear to us which incisor has been lost in each jaw of *Dasyurus*, so we will simply call them I1 4 above and i1 3 below

We next examined a three day old embryo measuring 7 mm GL and 4 mm HL (see fig 6 in Hill and Osman Hill, 1955) Two small deciduous incisors were in an early bud stage rostrally in the upper jaw The moderately sized deciduous canine was in a more distinct early bud stage It had a more darkly stained abnormal buccal portion and a more normal pale stained lingual portion Based on later developing stages, the darkly stained buccal portion represents the primordium of the rudimentary deciduous canine, and the more normal lingual portion represents the primordium of the successor canine These modified relationships for the developing deciduous and successional incisors and canines were

Table 1 Development of *Dasyurus viverrinus* upper postcanine dentition

Stage	dP1	dP2	dP3	P3	M1	M2	M3	M4

previously described in detail for marsupials (Luckett, 1993). The dental lamina was reduced distal to the developing canine. The lamina became thickened again distally at the level of the rostral end of the developing eye. It then gave rise to a moderate size early to middle bud stage dP3. The dental lamina and the maxillary bone disappeared distal to the dP3 bud.

In a slightly older embryo, 5 6 days old and measuring 8 mm GL and 4 5 mm HL (see fig 7, Hill and Osman Hill, 1955, and our fig 1b), three early developing incisors are now evident in the premaxillary region of the upper jaw The anterior two incisors are moderately sized and flattened in the early to middle bud stages The third incisor is moderately large and more spherical in the middle bud stage, and is located nearer the distal end of the premaxilla. It has a smaller darkly stained buccal portion and a larger lingual lobular

portion with lighter, normal appearing cells Based on its appearance in later developmental stages, these represent the buccal deciduous incisor and the more normal appearing lingual successor incisor

A moderately large late bud to early cap stage canine develops at the rostral extent of the maxilla. This also consists of a smaller darker buccal portion and a larger lingual paler staining portion, representing the future deciduous and successor canines, respectively The dental lamina is reduced distal to the developing canine and continues distally towards the level of the middle of the eye. At this region, the dental lamina enlarges and gives rise to a moderately large early cap stage dP3, formed by invagination of the underlying dental papilla cells (see fig 2b for an example) The dental lamina then disappears a short distance distal to this tooth, near the distal end of the eye

In the lower jaw, three developing incisors are in early- to late cap stages at the rostral extent of the dentary The di1 is in a late cap stage, with possible odontoblasts buccally and a lingual projection for an early successor bud for i1 The di2 has an early cap stage buccally and a distolingual projecting lamina for a possible successor i2 The smaller di3 has a less distinct buccal early cap with a relatively indistinct lingual successional lamina The moderately sized dc is in a late bud stage with a lingual successional ridge The dental lamina continues distally as a thin ridge with no suggestion of a dp1 or dp2 The dental lamina then thickens again distally, beneath the level of the distal portion of the eye, and gives rise to a moderately large late bud to early cap stage dp3 The dental lamina then ends distal to this developing tooth

In a 10 day old pouch young with a 6 5 mm HL and a 10 10 5 mm GL (see fig 9 in Hill and Osman Hill, 1955), there is little change in the developing incisor and canine regions of the upper jaw The dental lamina immediately distal to the canine exhibits a somewhat flattened early bud like thickening for a possible primordium of dP1, but this is not very distinct The dental lamina is then reduced and extends distally At the level of the middle portion of the eye, the dental lamina thickens again and gives rise to a moderately large early cap stage dP3 The dental lamina then ends distal to this tooth In the lower jaw, there is also a moderately sized early cap stage dp3 and no trace of a developing dp1

In a slightly larger 10 day old pouch young (7 mm HL and 11 mm GL), several distinct changes have occurred compared with the preceding specimen The developing incisor region remains similar, whereas the deciduous canine has a tiny buccal nodule associated with a large distolingual projecting late bud to early cap stage successor canine in the upper jaw Immediately following the canine is a tiny, somewhat flattened, probable early bud for dP1 The dental lamina is reduced distal to this early bud and extends distally to underlie the eye, where it enlarges to form a moderately sized middle cap stage dP3 There was no distinct swelling of the dental lamina between the dP3 and the probable early bud stage dP1. The dental lamina extends slightly distal to dP3 before it disappears

Note that in the early developing pouch young, there is little space in the jaws for the developing anterior dentition, due in part to the greatly enlarged tongue and its intimate association with the large nipple (fig 3) This often results in great compression and flattening of the more anterior developing teeth, whereas there is less compression distally in the region of the developing dP3 and molars

In the lower jaw, there is also a small, flattened early bud stage for dp1 The dental lamina is then reduced as it extends distally to form a moderately sized early to middle cap stage dp3 The dental lamina then ends distal to dp3 As in dasyurids with three premolars, the sequence of early development for the premolars in both jaws is dP3 ⮕ dP1 ⮕ dP2 As noted in this and later stages, it is the late developing dP2 that is lost in both jaws of dasyurids with only two premolars

In an older 14 day old pouch young, with 8 mm HL and 13 mm GL (see fig 10 in Hill and Osman Hill, 1955, and our fig 1c), the developing relationships for dI1 and dI2 in the upper jaw were similar to those of the previous stage In contrast, dI3 has an early cap knot enclosing a tiny dentinal arc The small distolingual successional bud for I3 is still relatively small A small buccal epithelial knot is evident for dC, and there is a large middle bud stage successor for the canine that is associated with a deep maxillary alveolus A small, flattened late bud to early cap dP1 follows the canine immediately, and then the dental lamina is reduced distal to this There is a possible slight swelling of the dental lamina beneath the anterior end of the eye, but this is not very distinct The dental lamina is then reduced distal to this slight swelling The dental lamina enlarges further distally and gives rise to a moderately sized early to middle bell stage dP3 beneath the middle third of the eye (see fig 2c for a middle bell stage tooth) This tooth is still intact with its primary dental lamina origin A flattened lingual successional lamina extends mesial to dP3 Distal to dP3 is a moderately sized late bud stage M1 underlying the distal end of the large eye The dental lamina ends distal to this tooth

In the lower jaw, the di1 is small and cap like, enclosing thin distinct dentin Distolingual to this is the larger early bud stage successor i1 The di2 is also a small cap with an irregular dentinal fragment, a slightly larger successor i2 is placed distolingually in a late bud to early cap stage The tiny di3 cap lacks dentin, and its distolingual successor ridge lacks a distinct successor tooth The small, dark cap for dc lacks dentin and has a distolingual middle bud stage successor canine The small, flattened dp1 follows immediately and is in the late bud to early cap stage There is no distinct evidence for a dp2 swelling Somewhat more distally there is a small middle bell stage dp3 with a short, flattened lingual successional lamina Immediately distal to this tooth is a moderately sized early bud for m1 The dental lamina disappears distal to this developing tooth

In a slightly larger 14 day old pouch young (13 5 mm GL and 8 mm HL; see fig 10 in Hill and Osman Hill, 1955), some notable changes are evident in the canine and postcanine dentition The successor canine is now in the early to middle bell stage in the upper jaw. The tiny, flattened dP1 is in the early cap stage The dental lamina becomes reduced distal to this tooth and then enlarges slightly to form a possible primordium for a rudimentary dP2 However, the dental lamina is reduced distal to this slight swelling and then enlarges further distally and gives rise to a moderately large middle to late bell stage dP3 This tooth has moderately developed stellate reticulum, and a short, slender lingual successional lamina extends mesial to this tooth (see fig 2d for a late bell stage with a lingual successional lamina) The dP3 lies beneath the middle region of the eye The primary dental lamina extends distal to dP3 and gives rise to a moderately large late bud M1 beneath the distal region of the eye The dental lamina then disappears distal to this bud

In the lower jaw, the successor canine is now in the late bud to early cap stage This is followed immediately by the small, elongate late bud to early cap stage dp1. The dental lamina is slightly swollen distal to this tooth, but this is not very significant Further distally, the small dp3 is in the late bell stage with moderately developed stellate reticulum but no
Figure 3 Transverse section through the head at the level of the developing eyes in a 10 day old *Dasyurus viverrinus* embryo 7 mm head length Note the close compression between the large tongue (T) and the nipple (N) No developing teeth are evident

dentin. There is a lingual successional lamina that extends mesial to dp3 and terminates with a slight bud like swelling Distal to dp3 is a large middle bud stage m1, and then the dental lamina disappears distal to this

In a slightly older pouch young (13 15 mm GL and 9 mm HL) estimated to be 15 16 days old, a significant change has occurred in the postcanine region of the upper jaw. The small dP1 is in the early cap stage and the dental lamina is greatly reduced distal to this tooth without any suggestion of a swelling for a rudimentary dP2 Further distally, the small to moderate sized dP3 is in the late bell stage with thin dentin on its apex. The tooth is relatively superficial with a short, intact primary dental lamina stalk to the oral epithelium. The tooth lies beneath the anterior of the eye. The slender lingual successional lamina extends mesial to the tooth and then enlarges to form a moderately sized early cap stage successor P3. The successor P3 extends mesially beneath the anterior margin of the eye. Distal to this, a moderately large middle to late cap stage M1 develops beneath the level of the middle of

the eye. The dental lamina then disappears distal to this tooth.

In the lower jaw, the dp1 is a moderately sized early cap stage. The dental lamina is reduced distal to this tooth, there is a slight swelling distally, but this is not very distinct Further distally, the dental lamina enlarges again and gives rise to a small to moderately sized, somewhat abnormal dp3 with an irregular, moderately developed dentinal cap. There is a short, primary dental lamina stalk to the oral epithelium. The tooth is in a shallow bony alveolus and has a flattened lingual successional lamina. Distal to this tooth is a large middle bell stage m1 The dental lamina disappears distal to the developing molar. In both jaws, the dP3 appear to be relatively smaller than in earlier stages and they lie closer to the oral epithelium.

In the later developmental stages, we will only discuss the postcanine development of the *Dasyurus* pouch young because there is little controversy concerning the development of the incisor and canine regions In a 19 day old pouch young (17 mm GL and 10 mm HL, see fig 11 in Hill and Osman

Hill, 1955), the small dP1 is somewhat flattened or compressed and has now attained the early bell stage in the upper jaw The dental lamina is reduced distal to this tooth and becomes detached from the oral epithelium The dental lamina becomes reattached further distally and forms an early bud like swelling, this possibly represents the rudiment of a dP2 The dental lamina is then reduced again and extends further distally, it then enlarges to form a small late bell stage dP3 There is moderately developed dentin but no enamel on this small tooth It lies beneath the middle of the eye in a shallow bony alveolus A lingual successional lamina extends mesially from dP3 and forms a slight bud like thickening As noted in the later developmental stages, this thickening is the primordium for the later developing successor P3 The dental lamina extends distal to dP3 and then enlarges to form a moderately large middle bell stage M1 This tooth lies beneath the distal half of the eye; the dental lamina disappears distal to this tooth

In the lower jaw, dp1 is a moderately sized, late cap to early bell stage tooth with a shallow bony alveolus The dental lamina is slightly swollen distal to this tooth (possibly representing the site of the lost dp2), then further distally, the dental lamina thickens again and gives rise to a small late bell stage dp3 with a moderately developed layer of dentin The lingual successional lamina of this tooth extends mesially, where it is slightly thickened terminally The dental lamina extends distal to this tooth and gives rise to a large middle to late bell stage m1 The dental lamina disappears distal to this tooth

In a later pouch young of 19 20 days old (16 18 mm GL), sectioned by Dr Louis Bolk, the dP1 is a small tooth in the late cap to early bell stage in the upper jaw The dental lamina distal to this tooth is detached from the oral epithelium There is no trace of a possible rudimentary dP2 Further distally, the dental lamina reappears and gives rise to a small, late bell stage dP3 with moderately thick dentin and a thin film of early enamel The lingual successional lamina of dP3 extends mesially and gives rise to a small late bud to early cap stage successor P3, which lies anterior to dP3 (see fig 2e for a late bell stage dP3 and its successor early cap stage P3) Distal to dP3, the dental lamina gives rise to a moderately large early to middle bell stage M1 The dental lamina then disappears distal to this tooth

In the lower jaw, the moderately sized dp1 is in the early bell stage The tooth is somewhat compressed and lies in a shallow bony alveolus There is only a slight possible swelling of the dental lamina distal to this tooth in the region of the missing dp2 Further distally, the dental lamina thickens again and gives rise to a small late bell stage dp3 with a moderately thick arc of dentin There is also a thin layer of darkly stained enamel The slender lingual successional lamina adjacent to dp3 extends mesially and is enlarged as a slight early bud like swelling for the future successional p3. The dental lamina is reduced distal to dp3 and then enlarges again to form a large middle to late bell stage m1 Distal to this tooth is a moderately large late cap stage for m2 The dental lamina disappears distal to this tooth

In another 19 20 day old pouch young (10 mm HL and 16 17 mm GL), there are slight advancements for some of the developing teeth A moderately sized dP1 is in the early bell

stage in the upper jaw. There is no distinct evidence for a rudimentary dP2 swelling distal to this tooth The dental lamina thickens further distally and gives rise to a small to moderately sized late bell stage dP3 with moderately developed dentin on its crown There is a shallow bony alveolus for the tooth, which lies beneath the anterior third of the eye The lingual successional lamina of dP3 extends mesially and thickens to give rise to a small early cap stage successor P3 Distal to the dP3, the dental lamina thickens again and gives rise to a moderately large middle bell stage M1 This tooth is positioned beneath the middle of the eye The dental lamina thins and then disappears distal to M1

In the lower jaw, a moderately sized dp1 is in the late cap to early bell stage There is no distinct evidence for a rudimentary dp2 distal to this tooth Further distally, there is a small, somewhat abnormal dp3 with a moderately developed dentinal arc but no stellate reticulum The lingual successional lamina of dp3 is slightly thickened mesially and then gives rise to a small middle bud stage successor p3 further anteriorly Distal to dp3, the dental lamina enlarges and gives origin to a large middle to late bell stage m1 Distal to this tooth, the dental lamina gives rise to a moderately sized late cap stage m2 The dental lamina then disappears distal to this tooth Note that in the 19 20 day old pouch young, the dentition in the lower jaw is accelerated in its development compared with that in the upper jaw, this trend continues to increase in later developmental stages

In a later 25 day old pouch young (20 mm GL and 12 5 mm HL; see fig 12 in Hill and Osman Hill, 1955, and our fig 1d) that has been sectioned longitudinally, dP1 is a small to moderately sized tooth in the middle to late bell stage in the upper jaw (fig 4) As in the previous stage, there is no suggestion of a dP2 rudiment Further distally, the small to moderately sized dP3 has relatively thick dentin and thin enamel The tooth is located beneath the anterior ⅓ of the eye The lingual successional lamina of dP3 extends mesially and thickens to form a moderately large early to middle cap stage successor P3 The deciduous and successor P3 appear to arise from a common primary dental lamina stalk This is due to the partial fragmentation of the primary dental lamina stalk in later stages of development (compare fig 4 with 2e) Distal to the developing dP3 P3 complex, the M1 is now in a large late bell stage with possible early odontoblasts but no dentin This tooth underlies the middle of the eye. A moderately sized early cap stage M2 develops distal to M1 The dental lamina then disappears distal to this tooth

In the lower jaw, dp1 is now a moderately large middle bell stage tooth, developing immediately distal to the large developing canine There is no distinct evidence for a rudiment of dp2 Further distally, the small to moderately sized dp3 is partially covered with a thick layer of dentin and a thin layer of enamel Mesiolingual to the small dp3, the lingual successional lamina gives rise to a larger early bud stage p3 Further distally is a large late bell stage m1 with moderately developed dentin on the apex of the tall protoconid Distal to this tooth, the dental lamina gives rise to a large middle to late bell stage m2 A possible early bud for m3 lies distal to this tooth, but problems with the tissue make it difficult to be certain of this
Figure 4 Parasagittal section through the dentition in a 25 day old pouch young 12 5 mm head length showing the developing teeth between dP1 and M2 in the upper jaw. Arrowhead refers to the site of the missing dP2. Abbreviation D location of developing dP3 follicle

In a 30 35 day old pouch young (23 24 mm GL and 13 5 mm HL, see fig 13 in Hill and Osman Hill, 1955), the dP1 is now a moderately sized tooth with moderately thick dentin and thin to moderately developed enamel on its crown in the upper jaw The tooth lies in a shallow bony alveolus, just below the oral epithelium. This is related in part due to the large canine that partially underlies the smaller dP1 throughout its length There is no trace of a rudimentary dP2 Further distally, the dental lamina thickens and gives rise to a small, somewhat elongate dP3 with moderately thick dentin and a partially disrupted layer of enamel The tooth lies anterior to the developing eye The lingual successional lamina of dP3 extends mesially and gives rise to a larger moderately sized late bell stage successor P3 with odontoblasts and a thin layer of predentin on its crown The P3 extends both anterior and posterior to dP3 because of its larger size. There is a normally sized developing bony alveolus for P3, whereas a distinct bony alveolus is lacking for the small dP3 Instead, the small deciduous tooth lies more superficially, in the apex of the deeper alveolus for the larger P3 Distal to the dP3 P3 complex, the large M1 has moderately thick dentin and thin enamel on its elevated metacone. There is a flattened residual lingual lamina along the extent of the tooth. This tooth lies beneath the anterior half of the eye. A moderately large middle to late bell stage M2 lies beneath the distal half of the eye The dental lamina disappears distal to this tooth.

In the lower jaw, dp1 is a relatively large tooth with moderately developed dentin and thin enamel on its apex. There is no suggestion of a rudimentary dp2 Further distally, the small dp3 has a relatively thick dentinal arc overlain by a thin film of enamel The enamel is covered by inactive cuboidal ameloblasts Lingual to the small abnormal dp3 is a thin successional lamina, this extends further mesially and gives rise to a moderately large early to middle bell stage p3 with a

loosening of its stellate reticulum. Distal to the dp3 p3 complex, the m1 is a large tooth with moderately thick dentin and thin to moderately developed enamel on the apex of its tall protoconid The tooth has a short, flat residual lamina. Distal to this tooth is a large m2, also with moderately developed to moderately thick dentin and thin enamel on its tall protoconid The m2 also has a short, flat residual lamina. A moderately large m3 lies distal to m2 and is in the middle to late bell stage. The dental lamina disappears distal to this tooth.

Another pouch young 30 35 days old (23 mm GL) was sectioned by Louis Bolk and showed some small differences with the previous specimen. The dP1 is moderately sized and is in the late bell stage with early odontoblasts and thin predentin in the upper jaw. The dp1 has a short, flat lingual successional lamina. Again, there is no suggestion of a rudimentary dP2 The small, somewhat abnormal dP3 has moderately thick dentin and possibly a thin film of enamel Mesio lingual to dP3 is a moderately sized late bell stage P3 with very early odontoblasts The elongate lingual successional lamina is fragmented in places and it is not clearly connected to dP3, in contrast to earlier stages Distal to dP3 is a large late bell stage M1 with moderately developed dentin and thin enamel on the tall metacone. A prominent, flattened residual lamina is present lingually Distal to this tooth is a moderately large middle to late bell stage M2 The dental lamina disappears distal to this tooth

In the lower jaw, the moderately large late bell stage dp1 has thin predentin on the apex of its single cusp, it immediately follows the large canine There is no suggestion of a rudimentary dp2 Further distally is a small, abnormal dentinal mass for the rudimentary dp3 with a thin layer of enamel on the surface of the dentin The primary dental lamina connection to the oral epithelium persists Anterior to the abnormal dp3 is a moderately sized middle to late cap stage p3 Only a few fragmented epithelial nodules represent

the earlier remnants of the lingual successional lamina from dp3 Distal to dp3 is the large m1 with moderately thick dentin and thin to moderately developed enamel on the apex of its tall protoconid A thin, flattened residual lamina is evident mesially Distal to this is a large late bell stage m2 with moderately developed dentin and thin enamel on the apex of the tall protoconid There is also a prominent, short residual lamina lingually Distal to this tooth is a moderately sized early bell stage m3, the dental lamina then disappears distal to this tooth

In a later pouch young of about 41 days old (29 mm GL and 18 mm HL, see fig 14 in Hill and Osman Hill, 1955), also sectioned by Louis Bolk, further changes occurred, especially with regards to the dP3 and P3 in both jaws In the upper jaw, the small dP1 now has moderately thick dentin and moderately developed enamel on the apex of the unicuspid tooth There is a short, flattened lingual successional lamina, and again no trace of a rudimentary dP2. Further distally, there is a small dP3 with moderately thick dentin and moderately developed enamel Ameloblasts are low cuboidal and probably are no longer functional Fragmented strands of the lingual successional lamina extend anteriorly and give rise to a moderately sized late bell stage successor P3 with thin early predentin on its apex Further distally, the large M1 appears, it has moderately thick dentin and enamel on its tall disto buccal metacone Distal to this tooth is a large late bell stage M2 This tooth also has an elevated disto buccal cusp that has odontoblasts and a very thin layer of predentin Following this tooth is a moderately sized early to middle bud stage M3 The dental lamina then disappears distal to this developing tooth

In the lower jaw, dp1 is a moderately sized tooth with a relatively thick layer of dentin and a moderately developed layer of enamel (partially disrupted) Its primary dental lamina stalk is still attached to the oral epithelium Only a slight suggestion of the thin lingual successional lamina is evident mesially There is no trace of a rudimentary dp2 Distal to dp1 is a very small, abnormal dp3 with a prominent dentinal mass There is also a very thin film of enamel, although there are no distinct remnants of ameloblasts The tooth is considerably reduced in size compared with earlier developmental stages The primary dental lamina connection of dp3 with the oral epithelium and its lingual successional lamina are also broken in places Nevertheless, the fragmented lingual successional lamina extends mesially and gives rise to a moderately large late bell stage successor p3 The p3 has well developed stellate reticulum and possibly early odontoblasts, although this is not clear The tiny dp3 lies more superficial than its larger successor and lacks a distinct bony alveolus

Distal to dp3 is a large m1 with thick dentin and moderately thick enamel on its tall, mesio to buccal protoconid The tooth lies in a deep bony alveolus Distal to m1 is a large m2 with moderately thick dentin and moderately developed enamel on its tall protoconid Further distally, m3 is a moderately large tooth in the late bell stage with a moderately developed layer of dentin on its tall protoconid There are also early ameloblasts on the tooth cusp, but no enamel There is a well developed lingual residual lamina mesially on the tooth Distal to this tooth is a possible early

bud for m4 developing on both sides of the jaw, but tissue disruption makes this difficult to confirm The dental lamina disappears distal to this region

Later development and eruption of the dentition in *Dasyurus viverrinus*

We would like to have been able to microscopically examine later developmental stages of the dentition in *Dasyurus viverrinus*, but at the time we were working at the Hubrecht Laboratory of Comparative Embryology, later stages were not available Many older specimens, from 46 days old to about 120 days old, were described by Hill and Osman Hill (1955), but only a few brief comments were provided by them concerning the early eruption of a few teeth Presumably, these later stages of alcohol specimens were included in the Hill collection when it was moved with the Hubrecht collection to the Museum fur Naturkunde

Concerning the later development and eruption of teeth in *Dasyurus viverrinus*, Hill and Osman Hill (1955) cited the earlier studies by Thomas (1887) and especially Woodward (1896), and accepted their beliefs that P3 is the tooth that has been suppressed in this species with two premolars They all agreed that a vestigial dP3 developed in the jaws and that the lingual successional lamina of this tooth was much swollen and probably represented a rudiment for the successor P3, although it probably does not develop much further All agreed that the vestigial dP3 is present but does not erupt and that the swollen primordium of P3 does not differentiate much further or erupt

It seems clear to us that none of these authors microscopically examined later developmental stages of *Dasyurus viverrinus* beyond the "much swollen" stage of P3 In our studies, this stage occurred at 15 20 days of development Indeed, in some 19 20 day old pouch young, the successor P3 was already in the late bud to early cap stage Between 20 and 41 days of development in our study, the P3 developed normally in both jaws, attaining the late bell stage In contrast, the dP3 in both jaws became relatively smaller and more abnormal in these later developmental stages, this would be consistent with continued reduction and non eruption of dP3 in later stages

The absence of a developing dP2 and the normal development of the successor P3 in the 25 41 day old pouch young in our study provide a strong basis for our belief that dP1 and P3 are the two erupting premolars in both jaws of later developmental stages in *Dasyurus viverrinus* Hopefully, future investigators will microscopically examine the later developmental stages and early eruption of the jaws in *Dasyurus viverrinus* to corroborate (or refute) our hypothesis of dental homologies

Comparison of *Dasyurus viverrinus* with the three premolared dasyurids *Sminthopsis virginiae* (Luckett and Woolley, 1996) and *Antechinus stuartii* (Luckett and Hong Luckett, pers obs) shows that there is a similar pattern in the early postcanine development of the premolars in these two groups, despite the loss of one deciduous premolar in the *Dasyurus* species While the deciduous premolars differentiate

and develop in a posterior to anterior series (dP3 > dP2 > dP1) in both jaws of the didelphids *Didelphis* and *Monodelphis*, the dasyurids show a different developmental sequence of dP3 > dP1 > dP2. In *Sminthopsis virginiae*, a previous study showed that dP2 was relatively late in its initiation, not appearing until about 20 days of pouch young development (Luckett and Woolley, 1996). The same is true for *Antechinus stuartii*. As shown in our developmental series of *Dasyurus viverrinus*, it is this later developing dP2 that has been lost in this species with only two premolars. In our *Dasyurus viverrinus* series, it was during the 15 to 20 days of development that there was a slight suggestion of thickening of the dental lamina between dP1 and dP3, this probably represented a rudimentary attempt to develop a dP2. In the later stages of development, from 25 to 41 days, there was no longer any sign of a rudimentary dP2.

Another interesting and unusual condition in *Dasyurus viverrinus*, when compared with the dasyurids with three premolars, is the nature of the development of dP3 in both jaws. The dP3 is the first postcanine tooth to initiate differentiation in both jaws, as also occurs in all three premolared dasyurids examined, as well as in didelphids. In contrast with these marsupials with three premolars, however, the dP3 in *Dasyurus* undergoes an abnormal state of development in later stages in both jaws, including a relative reduction in size and having a relative superficial position in the jaw with only minimal development of a bony alveolus. This abnormal development of dP3 is even more noticeable in the lower jaw. There is a large amount of dentin but only minimal amounts of enamel. In contrast, the successional P3 is developing normally in both jaws and it is quickly larger in size and deeper in the jaw than its deciduous predecessor. Although we could not follow later stages histologically, it is the normal developing successor P3 that erupts adjacent to dP1 in both jaws. In contrast, we are unaware of any evidence for eruption of the small, abnormal dP3 in *Dasyurus viverrinus*.

Another significant difference between *Dasyurus viverrinus* and the dasyurids with three premolars is the accelerated rate of development and eruption of P3 in *Dasyurus*, when compared with these other dasyurids and with didelphids. In the 97 day old *Sminthopsis virginiae* examined by us (see Luckett and Woolley, 1996), M1–2 are erupted in both jaws and M3 is partially (??) erupted in the upper jaw. In the lower jaw, m3 is almost completely erupted and the protoconid of m4 is in an early stage of eruption. The dP1 to dP3 are erupted in both jaws, whereas the moderately large and well developed successor P3 is still unerupted in both jaws.

In contrast, there is no sign of an erupted or unerupted dP3 in either jaw of *Dasyurus viverrinus* at about 95 days old, and dP1 is in early eruption. The successor P3 is in early eruption at about 98 days old, this is about the same time as the early eruption of M1. These data on *Dasyurus viverrinus* eruption are from the study by Merchant et al. (1984), although we have changed the names of their premolars ("first and second upper premolars") to correspond to our more precise and correct terminology because they considered dP2 to be present and P3 to be lost. As with most other studies on *Dasyurus viverrinus*, Merchant et al. (1984) did not microscopically examine any of their extensive series of

developing pouch young. We also note that these authors found no trace of an erupted dP3 in earlier or later stages of development, this is consistent with our findings of abnormal development of dP3 in later stages of development.

Variation in the fate of dP3 within *Dasyurus*

Neither Hill and Osman Hill (1955) nor Merchant et al. (1984) could detect any evidence for the eruption of a rudimentary dP3 in *Dasyurus viverrinus*, and we have not seen such a tooth in any of the juvenile or subadult skulls that we have examined. However, in another *Dasyurus* species that we have studied, *Dasyurus albopunctatus*, we have noted similar developmental stages to those of *Dasyurus viverrinus*, as well as an unusual condition during later developmental stages and early eruption (Luckett pers. obs). Our specimens of *Dasyurus albopunctatus* consist of microscopic sections of two early pouch young and a larger number (26) of skulls of juvenile and subadult specimens with erupting postcanine dentitions.

In the youngest specimen (fig 5) that we examined microscopically (AMNH 195149, 12 mm HL), the postcanine region contained a moderately large late-bell stage dP1 with no
odontoblasts in the upper jaw. There was a diastema for the missing dP2 with no swelling of the dental lamina Further distally was a moderately sized dP3 with moderately thick dentin and moderately developed enamel Extending mesially from the dP3 was a lingual successional lamina that gave rise to an early to middle bud stage successional P3 Further distally was a large M1 with moderately developed dentin but no enamel. Distal to this was an early to middle cap stage for M2, the dental lamina ended distal to this tooth This specimen is very similar in its developmental features to that of our *Dasyurus viverrinus* 25 day old pouch young (12 5 mm HL) A later developmental stage of *Dasyurus albopunctatus* (AMNH 193967, 32 mm HL) was considerably advanced The dP1 had thick dentin and enamel, and again, there was no trace of a rudimentary dP2 in the upper jaw The now tiny calcified dP3 was elongate and slender, considerably reduced in relative size compared with the previous specimen, it was very close to the overlying alveolar margins Deeper in the jaw and lingual to this was a moderately large successor P3, with thick dentin and enamel This specimen was considerably more advanced in its development compared with our 41 day old *Dasyurus viverrinus*

In a slightly later juvenile skull of *Dasyurus albopunctatus* (AM M24313, skull damaged, not measured), the second to fourth incisors were in early eruption in the upper jaw and the canine was in an earlier stage of eruption The dP1 was ½ ^{2}₃ erupted and there was no trace of a dP2 Immediately distal to this, the moderately sized successor P3 was in very early eruption, less than that of dP1 Lying on the apex of the P3 crown was a tiny, elongate and pearl shaped dP3 on both sides of the jaw The tiny dP3 had a crown height of 1 3 mm on the right side and 1 4 mm on the left side The M1 was almost completely erupted and M2 was in early eruption In comparison with the data on *Dasyurus viverrinus* from Merchant et al (1984), this specimen would be 95 98 days old In the lower jaw, the incisors are almost completely erupted, as is the canine The dp1 is also almost completely erupted The successor p3 is about ^{2}₃ erupted and there is no trace of a tiny dp3 The m1 is almost completely erupted and m2 is about ½ erupted

In nine juvenile skulls of *Dasyurus albopunctatus* from later developmental stages that we examined, we could see the tiny dP3 lying adjacent to the erupting P3 in the upper jaw in skulls where the P3 was not completely erupted (see fig 6a d) It would be incorrect to say that the tiny dP3 were erupted, and we prefer to consider them to be *displaced* during the eruption of P3 The oldest specimen that we examined with the tiny dP3 was a partially damaged juvenile skull (AMNH 151980, 43 51 mm Skull Length) The dP1 was erupted and P3 was almost completely erupted on the right side of the upper jaw The M1 was erupted and M2 was almost completely erupted In the lower jaw, dp1, p3 m1 and m2 were erupted and m3 was about ¾ erupted As in all the juvenile specimens examined by us for this species, there was no trace of a dp3 in the lower jaw This specimen was briefly noted by Tate (1947, p 142) who stated that the "upper and lower fourth premolars are absent The milk P4, however, can still be detected" As we have shown in this and earlier developmental stages, it is dP2 that is the missing tooth in both jaws, and P3 (his fourth premolars) is developed in both jaws It was the

tiny dP3 (his "milk P4") that he detected in the upper jaw.

In later developmental stages of *Dasyurus albopunctatus*, in which P3 was completely or almost completely erupted in the upper jaw, the tiny dP3 was absent in most cases However, in a few instances of some specimens with P3 erupted, tiny tooth like fragments of a probable apical or basal remnant of dP3 were found unilaterally (AMNH 151973, 151971) The oldest juvenile that we found with a slender root remnant of dP3 unilaterally (fig 6d) was in a male (BBM NG 97868, 47 25 mm Skull Length) with dP1, P3, M1 and M2 erupted in the upper jaw, and M3 was about ½ erupted

We suggest that the pattern of dental development and eruption in *Dasyurus albopunctatus* is an intermediate condition between that of the dasyurids with three premolars that we have examined and *Dasyurus viverrinus* Both of our species of *Dasyurus* have a similar accelerated rate of development for the eruption of P3 at about the same time as M1 and M2, compared with that for the dasyurid species *Sminthopsis* and *Antechinus* with three premolars The greatly reduced dP3 adjacent to the erupting P3 in the upper jaw of *Dasyurus albopunctatus* is an intermediate condition between the presence of an erupted dP3 in the dasyurids with three premolars and its absence in *Dasyurus viverrinus*

Although we have not made an extensive search for rudimentary dP3 remnants in other species of *Dasyurus*, we suspect that they can and will be found in some of these species We have seen one such probable tiny dP3 in *Dasyurus geoffroii* and *Dasyurus hallucatus*, and we have seen a similar condition of accelerated eruption of P3 in these two species We also note that Archer (1975, p 255) reported the presence of a rudimentary spicule like tooth in the position of the "normally absent" dP3 in *Dasyurus geoffroii* (WAM M6370), we suspect this was also a dP3 fragment

A final thought Although *Dasyurus viverrinus* is considered to be extinct on mainland Australia, we hope that investigators in Tasmania will help complete our studies on the later development and eruption of the dentition in this species, which still exists there but is threatened Investigators there have studied many other aspects of the biology of this interesting species, and we hope that this paper will stimulate some to further support or challenge our findings on dental development

Acknowledgements

Figure 6 *Dasyurus albopunctatus* pouch young. a AMNH 190927 36.64 mm skull length. Erupting teeth in the upper jaw with canine about ½ erupted. The dP1 is almost completely erupted and P3 is in early eruption. A tiny slender dP3 is lying on the distal margins of the erupting P3 pointing posteriorly. Its apex is not evident. M1 is erupted and the M2 is about ¾ erupting not shown. b AMNH 221650 37.53 mm skull length slightly older than the preceding. The dP1 is erupted in the upper jaw and P3 erupting ½ 40. A tiny elongate dP3 is evident along the posterior margins of the erupting P3. c BBM NG 28247 37.89 mm skull length. The dP1 is erupted and the P3 is almost completely erupted in the upper jaw. A tiny slender and elongate dP3 is evident along the distal margin of P3 and its root extends distally beneath the anterior opening of the infraorbital canal. d BBM NG 97868 47.25 mm skull length. In this older young the P3 is almost completely erupted in the upper jaw. A tiny slender root remnant of dP3 is evident distal to the buccal end of P3.

Abstract
Gomon, M.F., Struthers, C.D. and Kemp, J. 2021. A review of the Australasian genus *Pseudophycis* (Gadiformes Moridae), redescribing its four species and resurrecting the name *Physiculus palmatus* Klunzinger, 1872, for the Australian Red Cod. *Memoirs of Museum Victoria* 80 59 99

The commercially fished Red Cod *Pseudophycis bachus* Forster in Bloch and Schneider, 1801, is shown on the basis of both morphological and genetic evidence to be confined to New Zealand waters. The separation of the closely related but distinct Australian cognate brings the number of species in the Australasian genus *Pseudophycis* to four. The name *Physiculus palmatus* Klunzinger, 1872, which was long thought to be a junior synonym of *Pseudophycis barbata* Gunther, 1862, is demonstrated to have been originally proposed for the Australian endemic *Pseudophycis palmata* (new combination) differs from *P. bachus* in having a prominent black blotch or spot basally on the pectoral fin that does not extend dorsally onto the body, in contrast to distinctly extending onto body, the second dorsal fin with 47 56 rather than 40 45 rays, the anal fin with 50 57 rather than 42 48 rays and the vertebral column with 47 50 rather than 44–46 total vertebrae. Diagnoses, colour descriptions, images and distributions for all four species and a key to members of the genus are provided

Keywords
Teleostei, Actinopterygii, morphology, re description, comparison, distribution, CO1

Introduction

In an annotated catalogue of gadiform fishes of the world, Cohen et al (1990) treated the morid genus *Pseudophycis* as comprising three species *Pseudophycis bachus* Forster in Bloch and Schneider, 1801, *P. barbata* Gunther, 1863, and *P. breviuscula* Richardson, 1846, all confined to the temperate waters of New Zealand and Australia. The taxonomy followed Paulin's (1983) review of New Zealand species of Moridae that concluded that only three are present in New Zealand and Australian waters, despite the historical confusion over which names apply to the various *Pseudophycis* species. Paulin did, however, observe meristic variations in fin ray and scale counts between New Zealand specimens and the limited number of Australian specimens of *P. bachus* at his disposal, saying "examination of a larger sample of Australian specimens might show some differences but, in view of the variability within species of Moridae, there would probably be little justification for separating the populations at the species level" (Paulin, 1983, p 92). Subsequent authors (e g Gomon in Gomon et al., 1994; Kuiter, 1993, Last et al., 1983, Paxton and Hanley in Paxton et al., 1989, Paxton et al., 2006,

Yearsley et al., 1999) dealing with temperate Australian fish biodiversity followed Paulin (1983) and Cohen et al. (1990) in treating the Australian Red Cod as conspecific with the New Zealand species

Smith et al (2008) detected genetic differences between Australasian samples of *Pseudophycis* using the CO1 locus Their work included eight samples of *P. bachus*, four each from Australia and New Zealand, six samples of *P. barbata* from Australia, but no samples of the third species, *P. breviuscula*. They found differences between the *P. bachus* samples from the two countries that were equivalent to differences between *P. barbata* and each of the two *P. bachus* morphs, suggesting species level differences between all three. These genetic discrepancies were supported by work of Kemp (2010), who observed that there are a number of differences between individuals from Australian and New Zealand waters and that morphometric and meristic characteristics of *Pseudophycis* species in Australian waters have been poorly documented She compared 50 Australian specimens with 160 from New Zealand, both series identified as *P. bachus*, and found

significant differences in mean values for the second dorsal (50 2 vs 42 8, respectively) and anal (52 1 vs 45 0) fin ray counts, as well as pyloric caeca (9 6 vs 6 0) These observations provided the incentive to further compare the Australian and New Zealand populations with each other and with the other two long recognised members of the genus, *P. barbata* and *P. breviuscula* The outcome was a recognition of four easily distinguished species in the genus and the initiation of research on the scientific name for the Australian Red Cod

The Australian Red Cod is a relatively common demersal species, distributed in the shelf waters of south eastern Australia (Gomon in Gomon et al , 2008) It is an important prey species for some high trophic level predators, including little penguins, *Eudyptula minor* (Chiaradia et al , 2003, Cullen et al , 1992, Montague and Cullen, 1988), Australian fur seals, *Arctocephalus pusillus doriferus* (Gales and Pemberton, 1994, Hume et al , 2004, Kirkwood et al , 2008, Littnan et al , 2007), and New Zealand fur seals, *Arctocephalus forsteri* (Page et al , 2005) The trophic role of Australian Red Cod as prey, coupled with its relatively common occurrence, suggests that this species is particularly important in Australian waters Humans include these fishes as part of the non targeted bycatch consumed annually, although the species is more frequently discarded than retained (pers comm M Tudman, Bycatch Reduction Program Manager, Australian Fisheries Management Authority, 2008)

This contribution provides a name for the endemic Australian Red Cod, a detailed description that distinguishes it from the New Zealand *P. bachus*, descriptions for the four species in the genus and a dichotomous key to the species

Methods

Morphometric methodology mostly followed Paulin (1983), Trunov (1990), and Markle and Melendez (1988), measurements were taken directly (point to point) except that measurements between fins were horizontal distances between vertical projections at the origins of each fin, caudal peduncle length was taken from the posterior end of the anal fin base to the hypural joint, caudal fin length was from the hypural joint to the fin tip, and lengths of gill rakers and filaments were taken at or adjacent to the angle of the gill arch In lists of specimens examined, numbers of specimens and their standard lengths in mm are placed in parentheses after registration numbers, except for lots containing only a single specimen where only the length is presented Meristic methods are those of Hubbs and Lagler (1947) where counts of unpaired fins and vertebrae were taken from radiographs, the number of trunk centra was counted from the cranium to the last centrum with pleural ribs and counts of tail centra exclude the urostyle Selected meristic and relative morphometric ranges for the four congeners are presented in Tables 2 4 Other materials examined are in the ichthyological collections of the Australian Museum (AMS), Natural History Museum (formerly British Museum [Natural History]; BMNH),

Australian National Fish Collection (CSIRO), Museums Victoria (NMV), Museum of New Zealand Te Papa Tongarewa (NMNZ), South Australian Museum (SAMA), Staatliches Museum fur Naturkunde, Stuttgart (SMNS) and Western Australian Museum (WAM)

Genetic material and sequences. A genetic analysis of mitochondrial cytochrome oxidase subunit I (COI) gene was carried out on 72 sequences from muscle tissues, representing 5 terminal taxa of the family Moridae

The dataset included 61 sequences from the BOLD database (www.boldsystems.org) and 11 sequences newly generated for this study (see Appendix 1 for list of material and BOLD and GenBank accession numbers, vouchers for tissues yielding sequences in the material examined lists are indicated by a dagger [†]), including 18 specimens of *Pseudophycis bachus* from New Zealand, 23 *P. barbata* from Australia and New Zealand, 12 *P. breviuscula* from Australia and New Zealand, 12 *P. palmata* from Australia, and 7 *Auchenoceros punctatus* from New Zealand as a morid outgroup

Genomic DNA was extracted from the 11 (7 *P. bachus* [including neotype], 2 *P. breviuscula* and 2 *P. barbata*) additional ethanol preserved muscle tissues (Appendix 1) using DNeasy blood and tissue kit (Qiagen) A fragment of the COI gene was PCR amplified and sequenced using thermocycling conditions and primers (FishF2 and FishR1) from Ward et al , 2005) PCR products were purified by digestion with the ExoProStar (Illustra) or with the Zymo DNA Clean and Concentrator (Zymo Research, USA), following the manufacturer's instructions PCR products were sequenced in both directions on an ABI 3730 (Massey University Genome Service, Palmerston North, New Zealand or Macrogen, Seoul, South Korea) Newly generated sequences were deposited in GenBank (see Appendix 1 for a list of voucher specimens and their accession numbers)

Phylogenetic analyses. All 72 sequences were individually aligned in ClustalW using the software Geneious Prime v10 0 5 The COI alignment contained no insertions or deletions Maximum likelihood, neighbour joining and maximum parsimony trees were used to visualise distance relationships within and between species, node support was assessed with 1,000 bootstrap replications of each tree For the maximum likelihood analyses, the most appropriate model of sequence evolution for each dataset was determined using the Akaike information criterion in ModelTest, the HKY + G model was selected (Hasegawa et al , 1985) because it was the best performing of 24 different nucleotide substitution models tested in the model selection option of MEGA version X (Kumar et al , 2018) A discrete gamma distribution was used to model evolutionary rate differences between sites (5 categories, +G, parameter 0 3772) In addition, a neighbour joining tree was estimated using p distances (uncorrected distances) The p distance is the proportion of nucleotide sites at which two sequences being compared are different It is obtained by dividing the number of nucleotide differences by the number of nucleotides

compared It does not make any correction for multiple substitutions at the same site, substitution rate biases (e g differences in the transitional and transversional rates), or differences in evolutionary rates between sites For the maximum parsimony analyses, a heuristic search algorithm with 1000 random addition sequence replicates and tree bisection and reconnection branch swapping methodology was used Nodal support was tested with 500 bootstrap pseudo replicates, with ten random addition replicates for each pseudo replicate

Multivariate analysis of morphological data

To investigate the *a priori* grouping by species, a canonical analysis of principal coordinates (CAP) was performed using normalised Euclidean distances between specimens (Anderson and Willis, 2003) CAP is equivalent to a classical discriminant analysis Leave one out mis classification error (Lachenbruch and Mickey, 1967) was used to obtain a direct measure of the ability of the CAP discriminant model to identify species on the basis of the 20 characters This cross validation provided a rigorous assessment of the distinctiveness of the four species of *Pseudophycis*. The following 20 characters, measured in 124 *Pseudophycis* specimens of the four species (see material examined), were used in the analysis anal fin base length, barbel length, caudal peduncle depth, caudal peduncle length, caudal fin length, first dorsal fin base length, first dorsal fin longest ray length, head length, orbit diameter, pectoral fin base width, pectoral fin length, pelvic fin length, postorbital length, pre dorsal fin length, pre anal fin length, pre pectoral fin length, pre pelvic fin length, pelvic fin origin to anal fin origin length, second dorsal fin base length, and snout length

Genus *Pseudophycis* Günther, 1862

Pseudophycis Gunther, 1862 350, type species *Lota breviuscula* Richardson, 1846, by monotypy
Austrophycis Ogilby, 1897 90, type species *Austrophycis megalops* Ogilby, 1897 (*P breviuscula*) by monotypy
Physiculus (*Pseudophycis*) Whitley, 1956 403, taxonomic decision

Diagnosis. Morid fishes with an elongate body Luminescent organs absent Snout broadly rounded in dorsal view, not projecting greatly beyond mouth, length about equal to interorbital width Eye diameter much less than postorbital length Each jaw with broad band of small, depressible, caniniform teeth of uniform size Vomerine teeth absent Chin with well developed, often small, barbel. Branchiostegal rays seven Gill rakers of outer branchial arch short or of moderate length Otolith with ostium approximately equal to the cauda (1 1 to 1 14), the crista superior as long as or longer than the crista inferior, otolith thickness 20 22% of its length (Paulin, 1983) Scales small, covering body and head, extending onto loose membranes enveloping the bases of dorsal and anal fins, lateral line pores at ends of short tubes from naked strip not associated with individual scales Two dorsal fins and one anal fin, first dorsal slightly taller than, immediately adjacent to and joined to second by low membrane, with 8 14 rays, first ray not

prolonged; second dorsal and anal fins with elongate bases, of nearly uniform height, caudal fin separate, rounded or truncate Ventral fins composed of five or six rays, the two outermost longest and projecting beyond fin membrane but not greatly prolonged

Etymology. The feminine name *Pseudophycis* is an amalgamation of the Greek words *pseudos*, meaning "lie" or "false", and *phykis*, "a fish living among seaweeds" (Brown, 1954) and the source word of the scientific name for the North Atlantic gadid genus *Phycis* Walbaum, 1792, in reference to the overall resemblance of species of the two genera to one another

Distribution. Species of the genus are endemic to coastal waters of temperate Australia and New Zealand

Remarks. Species referable to the genus *Pseudophycis* were described or treated as members of seven morid genera based on the superficial resemblances of the species in the genera to one another These include *Gadus* Linnaeus, 1758, type species *Gadus morhua* Linnaeus, 1758, by subsequent designation of Jordan and Gilbert (1883 802), *Enchelyopus* Bloch and Schneider, 1801, type species *Gadus cimbricus* Bloch and Schneider, 1801, by subsequent designation of Jordan and Evermann (1898 2560), *Lota* Oken, 1817, type species *Gadus lota* Linnaeus, 1758, by subsequent tautonomy (Fricke et al , 2019), *Lotella* Kaup, 1858, type species *Lota phycis* Temminck and Schlegel, 1846, by monotypy and *Physiculus* Kaup, 1858, type species *Physiculus dalwigki* Kaup, 1858, by monotypy (see species treatments for details) *Austrophycis* Ogilby, 1897, caused particular confusion until Sazanov (2001 343) identified the type specimen of *A. megalops* as *P. breviuscula* (Richardson, 1846) The genus *Pseudophycis* comprises four species

Genetic analysis. Concerted efforts to document genetic sequences for the CO1 gene across Australasian fish species as part of the Fish Barcode of Life project provided an additional means of testing suspect species concepts A preliminary comparison of sequences of New Zealand and Australian specimens identified as *P. bachus* and *P. barbata* in BOLD had already revealed potentially cryptic sister species on either side of the Tasman Sea Sequences for specimens identified as *P. bachus* had low divergence among specimens within Australia (0 002) and within New Zealand (0 000) but high sequence divergence in the pooled data (0 086) typical of species pairs (Smith et al , 2008 8, fig 5)

A comparison of a larger set of sequences for Australian and New Zealand specimens identified as species of *Pseudophycis*, plus sequences of specimens of *Auchenoceros punctatus* as an outgroup, generated a tree with five inferred species branches, four having a common basal node for vouchers identifiable as *P. barbata*, *P. breviuscula*, *P. bachus* and *P. palmata* (Ward pers comm , fig 1) Importantly, the branches of *P. bachus* and *P. palmata*, previously thought to be conspecific, are of about the same lengths as those of *P. barbata* and *P. breviuscula*, despite the morphological differences distinguishing the latter two (Table 1)

Key to species of *Pseudophycis*

1   Caudal margin truncate with angular corners in specimens larger than about 150 mm SL, central caudal fin rays distinctly shorter than those extending to the corners; basal portion of pectoral fin with distinct dark blotch or spot   2

‐   Caudal margin rounded with rounded corners, central caudal fin rays equal in length or longer than those extending to the corners, no distinct dark blotch or spot basally on pectoral fin   3

2.   Dark blotch or spot basally on pectoral fin extending dorsally onto body, second dorsal fin with 40 45 rays, anal fin with 42 48 rays, total vertebrae 44 46
                                                                Pseudophycis bachus

‐   Dark blotch or spot basally on pectoral fin not extending dorsally onto body; second dorsal fin with 47 56 rays, anal fin with 50 57 rays; total vertebrae 47 50
                                                                Pseudophycis palmata

3   Scales above lateral line 16 22, second dorsal fin with 54 59 rays, anal fin with 54 63 rays, pyloric caeca 14 20, total vertebrae 48 51   *Pseudophycis barbata*

     Scales above lateral line 7 9; second dorsal fin with 44 52 rays, anal fin with 49 56 rays, pyloric caeca 6 9, total vertebrae 42 45   *Pseudophycis breviuscula*

Pseudophycis palmata (Klunzinger, 1872)

Proposed name: Australian Red Cod (Australian Standard)

   Pseudophycis barbata (*nec* Gunther, 1862) Kuiter, 1993 59, fig. (description, in part)

Diagnosis. First dorsal fin with 10 12 rays, second dorsal fin with 47 56 rays, anal fin with 50 57 rays, total vertebrae 47 50, nostrils located about two thirds to three quarters of the way from snout tip to eye; gill rakers of outer arch of moderate length, almost as long near angle as opposing gill filaments, chin barbel short, 6 17% HL, scales above lateral line in oblique series from base of first dorsal fin ray 11 15, oblique rows of scales intersecting with lateral line 96 116, pyloric caeca 8 10, caudal fin truncate with angular corners in specimens larger than about 150 mm SL, middle rays shorter than rays extending to corners, dark blotch basally on pectoral fin not extending onto side above fleshy pectoral fin base A large species reaching at least 598 mm TL or approximately 532 mm SL (Kemp, 2010 26)

Description. (Values for non type specimens when different from type in parentheses, see Tables 2 4 for summary of selected meristic and comparative morphometric values) First dorsal fin 11 (10 12, rarely 10, first ray usually minute), second dorsal fin 56 (47 56, rarely 47 or 54 55), anal fin 55 (50 57, rarely less than 51), pectoral fin 22 (22 27), pelvic fin 5 (5 or 6, rarely 6), caudal fin 37 (35 41) rays, gill rakers 4 + 10 (3 4 + 9 11 12 15), lateral line pores not associated with individual scales, oblique scale rows intersecting with lateral line unknown (96 116), scales in oblique series above lateral line 15 (11 15), scales in oblique series below lateral line unknown (28 40), vertebrae 16 + 34 (15 18 + 31 34) 50 (47 50), pyloric caeca 10 (8 10)

Table 1 Estimates of evolutionary divergence over sequence pairs within (left) and between (right) species Kimura 2 parameter genetic distances as averages over all sequence pairs within species are in the left column, with standard error estimates on the right (left table) Genetic distances as averages over all sequence pairs between species are below the diagonal with standard error estimates above it (right table)

Figure 1 Hasegawa-Kishino-Yano maximum likelihood tree of 65 COI sequences from four purported species of *Pseudophycis* along with seven sequences for an outgroup species *Auchenoceros punctatus*. Percentage bootstrap values followed by bootstrap values in p-distance neighbour joining and maximum parsimony trees are given for all well supported nodes; 2 of 3 exceeding 80%. Specimen numbers are those of registered museum vouchers or sequence numbers in the Barcode of Life Database (BOLD; http://www.barcodinglife.org).

Figure 2 *Pseudophycis palmata* A, B CSIRO H 7366-01 265 mm SL Storm Bay, east of Variety Bay on North Bruny Island, Tasmania, Australia, fresh specimen, lateral view of body and lateral view of head and anterior body with black pectoral blotch respectively, photographs C Devine CSIRO. C SMNS 1589 holotype 172 mm SL Port Phillip, Hobsons Bay, Victoria, Australia, photograph C Struthers, NMNZ.
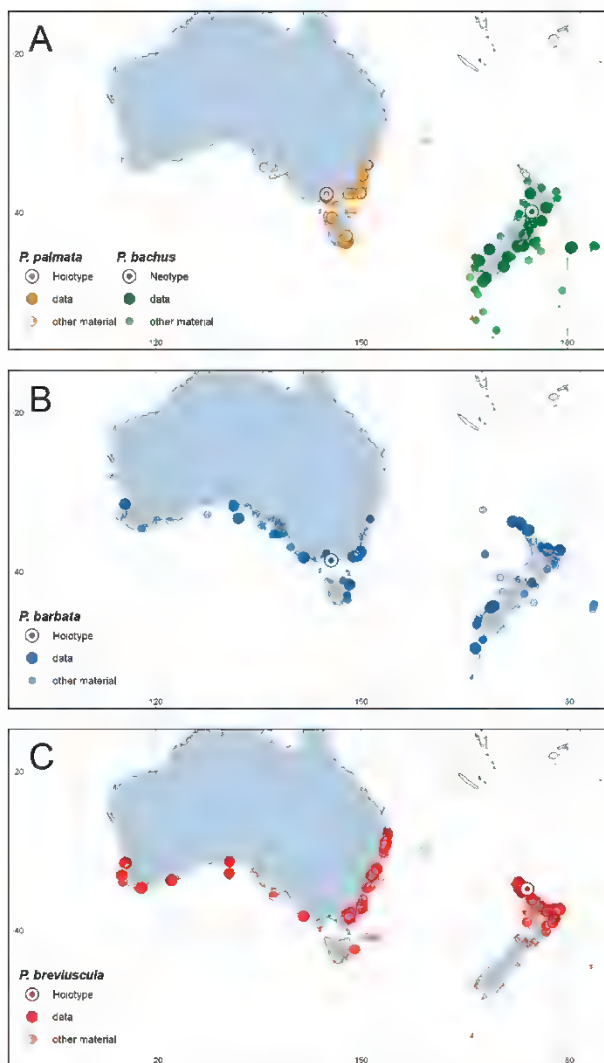

Figure 3. Collection localities for specimens of *Pseudophycis* spp. in museums. A. *P. bachus* green and *P. palmata* orange. B. *P. barbata* blue. C. *P. breviuscula* red.
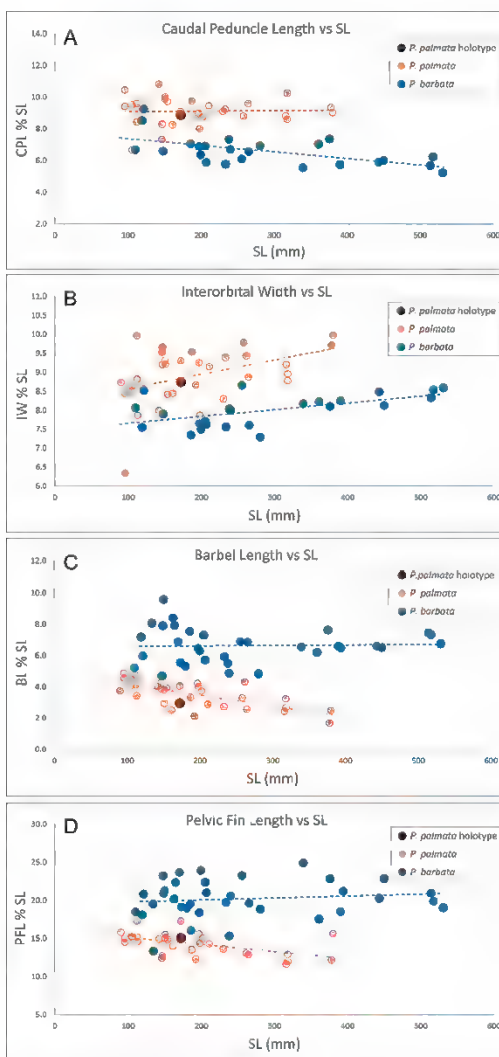

Figure 4 Plots of proportional measurements (% SL) against standard lengths for non-type specimens of *Pseudophycis palmata*, *P. barbata* and holotype of *P. palmata* A caudal peduncle length B interorbital width C barbel length D pelvic fin length
Figure 5 Scatter plot of canonical analysis of principal coordinates scores on the first and second canonical axes for 124 specimens of *Pseudophycis* including types

Body moderately slender, compressed laterally (fig 2), greatest depth at anal fin origin 23 6 (18 7 26 5)% SL, tapering uniformly from second dorsal fin origin to shallow caudal peduncle, caudal peduncle moderately short, 8 9 (6 7 10 8)% SL, strongly compressed, depth subequal to orbital diameter Distance between middle of anus and base of anal fin slightly less than half suborbital depth. Body cavity extending to above origin of anal fin

Head acute, of moderate size, length 26 1 (25 9 30 0)% SL, width 14 5 (15 3 21 6)% SL and depth 12 8 (10 2 18 4)% SL; snout of moderate length 7 6 (6 7 9 1)% SL, not projecting in advance of upper jaw, rounded in dorsal view Nostrils small, located about two thirds to three quarters of the way from snout tip to eye, distance from nostril to orbital margin less than (equal to or less than) diameter of combined nostrils, nostrils positioned above horizontal through centre of eye; posterior opening larger than (about half size to larger than) anterior opening, separated from it by raised skin flap, most of

margin (most or just posterior opening) encircled by tubular flap Interorbital broad, slightly convex Eye of moderate size, orbital diameter 28 0 (18 9 31 5)% HL, 1 33 (0 66 1 87) times in interorbital space, 2 41 (1 65 7 06) times suborbital distance, circular, upper edge of eye adjacent to dorsal margin of head in lateral view, transparent skin covering eye faintly pigmented near orbital dorsal margin Postorbital moderately long, 0 91 (0 85 1 01) times length of upper jaw Mouth large, terminal, upper jaw terminating posterior to (at or posterior to) vertical through posterior margin of eye. Jaw teeth caniniform, slightly curved, depressible, band of up to four or five irregular rows in upper jaw with distinct hiatus at symphysis, teeth in outer row more regularly arranged than in inner rows, band tapering near rear of jaw. Teeth of lower jaw similar in form to those of upper jaw, band of two or three rows with broader patch on either side of symphysis, tapering to single, widely spaced row posteriorly, rows almost contiguous across symphysis Vomerine teeth absent

Opercular bones strong; upper extremity of gill opening at horizontal through middle of eye, gill membranes continuous across isthmus. Gill rakers on outer arch slender, of moderate length, about 0.8 to 1.3 times length of opposing gill filaments, 8.4–12.2 times in head, their inner margin denticulate. Chin barbel short, subconical 11.3 (6.0–17.4)% HL.

Small cycloid scales covering all of head, including gular region and isthmus, and body except for branchiostegal membranes, surface of maxilla and premaxilla, lower lip and distal parts of fins, thick mucus covering obscuring scales and pores in freshly preserved material. Most head pores tiny, following main cephalic sensory canals, row of slightly raised pores from nostrils to tip of snout and then posteriorly just above lower edge of suborbital, row of enlarged mandibular pores on underside of lower jaw. Lateral line comprising widely spaced pores on short tubes arising from narrow scale less gap, anterior end curved upwards slightly, then gradually descending to lateral midline below posterior 25% of second dorsal fin, remaining on lateral midline posteriorly.

Membranes of first and second dorsal fins continuous at base, first dorsal originating distinctly behind vertical through pectoral fin base; anterior two thirds of second dorsal of uniform height, 10th to 12th ray from posterior end of fin longest, its height about 1.4 times length of 2nd ray at anterior end of fin, last ten or so rays progressively shorter, rays of both dorsal fins mostly unbranched, only last 13 to 16 rays, apart from last one to three, branched. Fleshy, fine scale covered basal sheath on third or more of first dorsal and anterior portion of second dorsal fins, fin rays interconnected by membranes to tips, sheath gradually decreasing slightly in coverage and thickness posteriorly, encompassing about half of second dorsal fin near its insertion, sheath extending onto body for anterior third of combined dorsal fin base, broadest anteriorly, narrower posteriorly. Profile of anal fin like second dorsal fin with comparable unbranched and branched rays. Anal fin enclosed in broad fleshy sheath like dorsal fins, sheath also extending onto body for anterior third or less of fin. Caudal fin truncate with distinct dorsoposterior and ventroposterior corners in adults, posterior margin with slight convex curve, longest rays to corners, middle rays about 85–90% length of longest rays, fin more rounded in juveniles, base of fin covered by indistinct sheath sharply demarcated from scales of caudal peduncle. Pectoral fin tip reaching (not quite to or to) vertical through anal fin origin, sixth or seventh ray longest. Pelvic fin inserted anterior to vertical through posterior edge of preopercle (more posteriorly in some specimens), outer two rays longer than inner rays, second ray longest, 15.1 (11.7–17.3)% SL, nearly twice length of subsequent ray, reaching vertical through first dorsal fin origin.

Fresh colour. (Based on images of non type material, fig 2A, B.) Medium brown above extending ventrally to about ventral portion of pectoral fin base, white below, suffused with pinkish hue, especially above anal fin base; lateral line slightly paler at least anteriorly. Underside of head, jaws and barbel white, sometimes tinged with pink. Dorsal, caudal and distal half of anal fins medium brown, proximal half of anal fin white, especially anteriorly, with pink hue, dorsal and anal fins with

fine black edge, posterior edge of caudal fin with broad black margin. Pectoral fin medium brown with semi circular black basal spot covering dorsal 80% of proximal edge of fin, extending little if at all onto side dorsal to fin base. Pelvic fin rays white with pink hue.

Preserved colour. Mostly pale (upper half of head and body pale dusky to dusky, lower half very pale, frequently pearly white. Dorsal, caudal and distal half of anal fins pale dusky, distal edges of dorsal and anal fins with fine dark margin, posterior edge of caudal fin broadly dark, pelvic fin, pectoral fin and basal half of anal fin very pale, pectoral fin with prominent dark spot (faded in type) covering dorsal half or more of basal edge, not extending onto side of body dorsally.

Etymology. The specific epithet *palmata* appears to be Latin for "embroidered with palm branches", although the reason for the name is unknown.

Distribution. Endemic to coastal temperate waters of south east Australia at least from Port Lincoln, Spencer Gulf, South Australia (34° 44' S, 135° 52' E, SAMA F2766), to Port Stephens, New South Wales (32° 49' S, 152° 05' E, AMS I 25865 003), including all of Tasmania (fig 3a). An unverified record at Coles Point, South Australia, 34° 22' 06" S, 135° 21' 09" E (SAMA F11864), may extend the distribution slightly farther to the west (fig 3A). Occurs on soft bottom habitat at 2–115 m.

Remarks. *Pseudophycis palmata* is closely related to the New Zealand *P. bachus*, with which it was confused (Gunther, 1880a: 28, McCulloch, 1921: 42, Ogilby, 1886: 48, Waite, 1904: 24). Both differ from the remaining two congeners by the possession of a black spot or blotch at the base of the pectoral fin and a truncated caudal fin margin in adults. The two also differ from the others in having the lower half of the body and the basal half or more of the anal fin mostly white, rather than tan to brown, although these areas are occasionally suffused with orange to pink in specimens of all four species. Morphometrically, the pair appear to have a deeper caudal peduncle (3.8–5.9, mean 4.7% SL vs 3.3–5.2, mean 4.4% SL), shorter barbel (1.7–4.9, mean 3.5% SL vs 4.7–9.6, mean 6.5% SL) and shorter or longer head (25.9–30.0, mean 27.4% SL vs 23.3–31.6, mean 28.8 in *P. barbata* and 23.4–26.0, mean 24.8% SL in *P. breviuscula*), as well as other relative lengths of features that correspond with the general body form. All four species in the genus are separable by vertical fin ray, scale and vertebral counts, as identified in the above key and in Table 2. Both *P. palmata* and *P. bachus* attain a large size, as does *Pseudophycis barbata* (well over 600 mm SL), while *P. breviuscula* is the smallest species, reaching only about 150 mm SL.

The two *P. bachus* like species are very similar to each other proportionally, although the eye of the Australian species is slightly larger than that of *P. bachus*, the orbital diameter 5.3–9.7, mean 7.4% SL vs 4.6–8.1, mean 6.2% SL, the paired fins proportionally shorter, pectoral fin 13.5–17.7, mean 15.8% SL vs 14.6–19.4, mean 17.1% SL and pelvic fin 11.7–17.3, mean 14.3% SL vs 11.5–21.1, mean 16.7% SL, and caudal fin similarly shorter 9.9–15.3, mean 12.2% SL vs 11.2–15.6, 13.7% SL. *Pseudophycis palmata* is readily

separable from *P. bachus* by the smaller pectoral fin blotch that fails to extend onto the body above the pectoral fin base It also differs subtly from *P. bachus* in having the distal half of the anal fin brownish with a fine black margin rather than whitish, like the basal half, and the black margin confined to the posterior lobe of the fin, if it is present at all The Australian cognate has fewer transverse scale rows (96 116 vs 102 136 in *P. bachus*) but more pyloric caeca (8 10 vs 6), anal fin rays (50 57 vs 42 48) and second dorsal fin rays (47 56 vs 40 45)

In the course of exploring the taxonomic identity of the Australian Red Cod, the species to which the name *Physiculus palmata* Klunzinger, 1872, is referable became less and less clear The name was regarded as a junior synonym of *P. barbata* for more than 80 years (McCulloch, 1929 129) Klunzinger's (1872) original description is inadequate for separating the three species of *Pseudophycis* occurring at or in the vicinity of the type locality A specimen (SMNS 1589) in the Stuttgart Museum, the repository of Klunzinger's type material, registered the year the name was published, apparently collected at the type locality and clearly identified by Klunzinger as that species, was regarded as a syntype by Fricke (1992 13, 2005 48) It is much smaller (173 mm SL) than the 50 cm length given in the description, implying Klunzinger was aware of or had other material The dark spot on the base of the pectoral fin that is diagnostic for the species, as well as dark pigment on the distal edge of the caudal fin, has completely faded The only other specimen of *Pseudophycis* (SMNS 2242) dating from that approximate time currently in the Stuttgart collection was identified by Klunzinger in 1877 and is unlikely to have been available when the description was published We therefore follow Fricke in regarding SMNS 1589 as the only known type

Although the three species occurring near the type locality are clearly separable by morphological characters, the colours and markings on the type specimen that would have been diagnostic have faded Meristic characters including vertebral numbers, fin ray and scale counts have ranges that overlap slightly in the two most likely candidate species, *P. barbata* and the Australian *P. bachus* cognate Unfortunately, the type specimen of *P. palmata* has meristic values that fall in the overlap zone for all but three characters, the number of scales above the lateral line 15 (11 15 in *P. bachus* like vs 16 22 in *P. barbata*), total caudal fin rays 37 (35 41 in *P. bachus* like vs 32 35 in *P. barbata*) and pyloric caeca 10 (8 10 in *P. bachus* like vs 14 20 in *P. barbata*) that favour its identity as the *P. bachus* cognate (Table 1) A comparison of relative morphometric values for the type with those of these two species, however, revealed clear support for the identity of the type as the *P. bachus* like species with eight of the type's relative measurements (head length, caudal peduncle length, caudal peduncle depth, post orbital length, interorbital width, barbel length, pelvic fin length and caudal fin length) positioned closer to the *P. bachus* like species proportional curves relative to standard length (e g fig 4) and curves for the same measurements (not head length) equally close to the proportional curve relative to its head length Only predorsal fin length has clearly different proportional curves for the *P.*

bachus like species and *P. barbata*, with the predorsal value for the type of *P. palmata* falling equidistant between the curves of the two species for that measurement

The diagnostics of a CAP analysis revealed that 96 8% of 124 specimens of *Pseudophycis* were correctly classified as their respective species based on the 20 characters examined By species, the percentage of individuals correctly classified by the CAP discriminant model was 96 6% for *P. palmata* (with one misclassified as *P. bachus*), 97 3% for *P. bachus* (with one misclassified as *P. palmata*), 94 3% for *P. barbata* (with one misclassified as *P. palmata*) and 100% for *P. breviuscula* Separation of the four species of *Pseudophycis* is shown in fig 5, with some overlap of *P. palmata* and *P. bachus* SMNS 1589 (holotype of *P. palmata*) is grouped within the other specimens of *P. palmata* and is well separated from *P. barbata* Consequently, the CAP analysis and fig 5 support the taxonomic decision to resurrect *Pseudophycis palmata* as the appropriate name for the Australian endemic previously thought to be conspecific with *P. bachus* Overlap of *P. palmata* and *P. bachus* is consistent with the historical confusion involving the two species

Despite its close relationship with *P. bachus*, the first known detailed description of this species appears to be that of McCoy (1878) who based his description of *P. "barbatus"* almost entirely on specimens of the Australian *P. bachus* like species That species was probably the common representative of the genus in the Melbourne markets at the time Meristic and morphometric data presented by McCoy appear to be entirely attributable to specimens of *P. palmata*, with only the illustration (McCoy, 1878 pl 20) based on a specimen of *P. barbata* Although several of McCoy's specimens were either lost or obscured by early collection practices, NMV A23366 001 is likely to be the specimen featured in the illustration, while counts and measurements were probably taken from NMV 43104, 43105, A841 and A23366 002. Other old NMV collection specimens of the new species that lack documented provenance probably comprised the remaining three Considering the frequent occurrence of this species at the type locality of *P. palmata*, together with the strong morphological support discussed above, we consider the name to be applicable to the Australian *P. bachus* like cognate Paulin (1983) failed to deal with the name in the synonymies of the three species he recognised

This species has the most restricted range of Australian *Pseudophycis* species, with no records of it west of Spencer Gulf, South Australia Its latitudinal limits approach those of *P. bachus* in New Zealand, as do those of the two species occurring in both Australia and New Zealand where bathymetrically feasible

Material examined Type Physiculus palmatus SMNS 1589 (172, holotype) Port Phillip, Hobsons Bay (northernmost section of Port Phillip Bay immediately south of Melbourne), Victoria

Physiculus bachus Fowler, 1940 758 (near Loba, New Zealand)

Physiculus (Pseudophycis) bachus Graham, 1956 166, Whitley, 1956 403, Whitley, 1968 40 (list)

Pseudophycis bachus Doogue and Moreland, 1982, 218, fig (misspelling)

Diagnosis. First dorsal fin 11 13 rays, second dorsal fin 40 45 rays, anal fin 42 48 rays, total vertebrae 44 46, scales above lateral line in oblique series from base of first dorsal fin ray 10 12, oblique rows of scales intersecting with lateral line 102 136, pyloric caeca 6, caudal peduncle moderately short 28 0 38 9% HL, barbel short, 8 6 16 9% HL, caudal fin truncate with angular corners in specimens larger than about 150 mm SL, middle rays shorter than rays extending to corners, dark blotch basally on pectoral fin extending well onto side above fleshy pectoral fin base, underside of head and body whitish, anal fin mostly whitish with faint narrow black distal margin only posteriorly, if at all A large species reaching at least 650 mm SL

Description. (Values for neotype with those for non type specimens when different in parentheses, see Tables 2 4 for summary of selected meristic and comparative morphometric values) First dorsal fin 11 (11 13, rarely 13, first ray usually minute), second dorsal fin 42 (40 45, usually 42 or 43), anal fin 45 (42 48, usually 45 47), pectoral fin 24 (22 25, rarely 22), pelvic fin 5, caudal fin 36 (33 39), gill rakers 4 + 10 (4 5 + 10 12 14 16), lateral line pores not associated with individual scales, oblique scale rows intersecting with lateral line 112 (102 136), scales in oblique series above lateral line 11 (10 12), scales in oblique series below lateral line 30 (26 34, rarely 33 or 34), vertebrae 16 + 29 (16 17 + 27 30 44 46), pyloric caeca 6

Body moderately slender, compressed laterally (fig 6), greatest depth at anal fin origin 19 5 (18 4 23 7)% SL, tapering uniformly from second dorsal fin origin to shallow caudal peduncle, caudal peduncle short, 8 5 (7 7 10 5)% SL, strongly compressed, depth less than orbital diameter Distance between middle of anus and base of anal fin less than suborbital depth Body cavity extending posteriorly to above origin of anal fin

Head acute, of moderate size, length 26 5 (25 9 29 6)% SL, its width 14 4 (13 4 17 7)% SL and depth 11 7 (10 2 15 6)% SL; snout of moderate length 7 5 (7 1 9 0)% SL, not

projecting in advance of upper jaw, rounded in dorsal view. Nostrils small, located about two thirds to three quarters of the way from snout tip to eye, distance from nostril to orbital margin equal to or greater than diameter of combined nostrils, nostrils positioned above horizontal through centre of eye, posterior opening larger than anterior, separated from it by raised skin flap, posterior opening with tubular flap encircling margin Interorbital of moderate width, very slightly convex Eye of moderate size, orbital diameter 21 1 (17 0 30 4)% HL, 1 58 (0 98 2 00) times in interorbital space, 2 20 (1 50 4 25) times suborbital distance, circular, upper edge of eye adjacent to dorsal margin of head in lateral view, transparent skin covering eye faintly pigmented near orbital dorsal margin Postorbital moderately long, 1 01 (0 89 1 22) times length of upper jaw Mouth large, terminal, upper jaw terminating at vertical through posterior margin of eye Jaw teeth caniniform, slightly curved, depressible, band of up to four or five irregular rows in upper jaw with distinct hiatus at symphysis, teeth in outer row more regularly arranged than in inner rows, band tapering near rear of jaw Teeth of lower jaw similar in form to those of upper jaw; band of two or three rows with broader patch on either side of symphysis, tapering to single, widely spaced row posteriorly, rows almost contiguous across symphysis Vomerine teeth absent Opercular bones strong, upper extremity of gill opening at horizontal through middle of eye, gill membranes continuous across isthmus Gill rakers on outer arch slender, of moderate length, almost as long near angle as opposing gill filaments, 12 8 (9 5 12 8) times in head, their inner margin denticulate Chin barbel short, subconical 12 0 (8 6 16 9)% HL

Small cycloid scales covering all of head, including isthmus and gular region, and body except for branchiostegal membranes, surface of maxilla and premaxilla, lower lip and distal parts of fins, thick mucus covering obscuring scales and pores in freshly preserved material Most head pores tiny, following main cephalic sensory canals, row of slightly raised pores from nostrils to tip of snout and then posteriorly just above lower edge of suborbital, row of enlarged mandibular pores on underside of lower jaw Lateral line comprising widely spaced pores on short tubes arising from narrow scale less gap, anterior end curved upwards slightly, then gradually descending to lateral midline below posterior 25% of second dorsal fin, remaining on lateral midline posteriorly

Membranes of first and second dorsal fins continuous at base, first dorsal originating vertically above pectoral fin base, anterior two thirds of second dorsal of uniform height, 7th to 9th ray from posterior end of fin longest, its height about 1 4 times length of 2nd ray at anterior end of fin, subsequent rays progressively shorter, rays of both dorsal fins mostly unbranched, only last 13 to 16 rays of second dorsal, apart from last one to three, branched Fleshy, fine scale covered basal sheath on third or more of first dorsal and anterior portion of second dorsal fins, fin rays interconnected by membranes to tips, sheath gradually decreasing in coverage and thickness posteriorly, encompassing about half of second dorsal fin near its insertion, sheath extending onto body for anterior third of combined dorsal fin base, broadest anteriorly, narrowing posteriorly Profile of anal fin like that of second

dorsal fin, although shallower posteriorly, with comparable unbranched and branched rays. Likewise, anal fin enclosed in broad fleshy sheath that is like that of dorsal fins, sheath also extending onto body for anterior third or less of fin. Caudal fin truncate with distinct dorsoposterior and ventroposterior corners in adults, posterior margin with little if any convex curve, longest rays to corners, middle rays about 85–90% length of longest rays, fin more rounded in juveniles, base of fin covered by indistinct sheath sharply demarcated from scales of caudal peduncle. Pectoral fin tip variably reaching almost to, to or past vertical through anal fin origin, sixth or seventh ray longest. Pelvic fin inserted anterior to vertical through posterior edge of preopercle (more posteriorly in some specimens), outer two rays longer than inner rays, second ray longest, 16 0 (11 5–21 1)% SL, nearly twice length of subsequent ray, reaching past a vertical through first dorsal fin origin.

Fresh colour. (Based on images of neotype, fig 6A, B.) Medium brown above extending ventrally to level of ventral edge of pectoral fin base, white below, suffused with pinkish hue, especially above anal fin base, lateral line slightly paler at least anteriorly. Underside of head, jaws and barbel white, tinged with pink. Dorsal and caudal fins medium brown, caudal paler with reddish tinge ventrally, anal fin white with pink hue; dorsal fins with fine black distal margin, caudal fin margin with broader, more diffuse black margin, anal fin with faint black distal margin, darkest posteriorly. Pectoral fin medium brown with semi circular black basal spot covering dorsal half of fin edge proximally, extending well onto side of body above fin base, ventroposterior margin of fin pale to translucent. Pelvic fin rays white with pink hue.

Preserved colour. Upper half of head and body pale dusky to dusky, lower half very pale, frequently pearly white. Dorsal and caudal fins pale dusky, distal edge of dorsal fin with fine dark margin, posterior edge of caudal fin broadly dark, anal fin very pale, distal edge of fin posteriorly with fine dark margin in some, pelvic fin, pectoral fin and basal half of anal fin very pale, pectoral fin with prominent dark spot covering dorsal half or more of basal edge that extends onto side above pectoral fin base.

Etymology. The name *bachus* is an altered spelling of *bacchus*, the Greek god of wine, adopted for the wine red colouration assumed shortly after capture but lost soon after death.

Distribution. Endemic to New Zealand, occurring around both the North and South Islands, and reaching the Chatham Islands in the east (fig 3A). A demersal species on soft bottom at 2–570 m depth.

Remarks. *Pseudophycis bachus* was originally described as *Enchelyopus bachus* Forster in Bloch and Schneider, 1801, based on Forster's manuscript description of "*Gadus bachus*", subsequently published by Lichenstein (1844 120). Forster's drawing No 180, on the back of which is pencilled "ex Queen Charlotte Sound", is evidently an illustration of the fish on which the description was based. Although both Bloch and Schneider (1801 53) and Lichtenstein gave the origin of the

specimen simply as "in the seas around New Zealand", Whitehead (1969 pl 11), Paulin (1983 91) and Fricke et al (2019) regarded Queen Charlotte Sound, the presumed collection locality of the specimen implied in the note on Forster's illustration, as the type locality. However, Hoare's (1982 269) reproduction of *Forster's Resolution Journal* has a footnote stating "*Gadus bacchus* of Descr. Anim., p 120 and Forster drawing 180 (undated). The description is from a specimen of 22 inches (559 mm), dated 13 April 1773" That date puts the type locality as Dusky Sound from a larger fish. Paulin (1983 92) provided a detailed discussion of the origin and various iterations of Bloch and Schneider's name.

An unfinished drawing by Parkinson (vol 2, no 5, ex Totarra 'nue, 404 mm tot 1) reproduced by Whitehead (1969 pl 11, here as fig 6C), has "*18, Blennius venustus*" pencilled on the reverse side and is the basis for Richardson and Gray's (1843 222) *Brosmius venustus*. The fish figured is clearly an example of *P. bachus*, despite the incomplete nature of the illustration. Totaranui is the Maori name for Queen Charlotte Sound. The scientific name is regarded as unavailable because no distinguishing features were provided by the authors (Fricke et al, 2019). The illustrated characters agree with those of specimens from New Zealand identified as *P. bachus*.

Because no type specimen of *P. bachus* is known (Fricke et al, 2019), the designation of a neotype for *P. bachus* is considered justified. A specimen (NMNZ P054828, 351 mm SL; fig 6a) collected from 2 5 km off the coast from Whanganui River bar, Whanganui, New Zealand, is proposed as the neotype for *P. bachus*. Accordingly, Whanganui, New Zealand, becomes the type locality of *P. bachus* under Article 76 3 (ICZN, 1999), replacing the original type locality Queen Charlotte Sound, New Zealand.

Material examined Neotype NMNZ P054828[†] (351) 2 5 km off the coast from Whanganui River bar, Whanganui, New Zealand, 39° 53' S, 174° 49' E, 18 m, C. Papple, 10 October 2012.

Diagnosis. First dorsal fin with 10 11 rays, second dorsal fin with 54 59 rays, anal fin with 54 63 rays, total vertebrae 48 51, scales above lateral line in oblique series from base of first dorsal fin ray 16 22, oblique rows of scales intersecting with lateral line 123 162, pyloric caeca 14 20, caudal peduncle short 13 5 18 6% HL, chin barbel of moderate length, 16 5 35 1% HL, caudal fin rounded without angular corners, the middle rays equal to or longer than rays above and below, no distinct, dark blotch basally on pectoral fin although fin base sometimes overall dark, underside of head and body tan to brown, anal fin tan to brown with distinct black distal margin A large species reaching at least 620 mm SL

Description. (Values for non type specimens when different from type in parentheses, see Tables 2 4 for summary of selected meristic and comparative morphometric values) First dorsal fin 10 (10 11), first ray small to minute, second dorsal fin 59 (54 59, rarely 59), anal fin 59 (54 63), pectoral fin 25 (24 27, rarely 24), pelvic fin 5, caudal fin 33 (32 35 rays), gill rakers unknown (3 4 + 8 11 12 14), lateral line pores not associated with individual scales, oblique scale rows intersecting with lateral line unknown (123 162), scales in oblique series above lateral line unknown (16 22), scales in oblique series below lateral line unknown (38 56, rarely less than 45), vertebrae unknown (14 16 + 33 37, rarely 37 48 51), pyloric caeca unknown (14 20)

Body of moderate depth, moderately compressed laterally (fig 7b), greatest depth at anal fin origin unknown (19 7 29 3)% SL, tapering uniformly from second dorsal fin origin to shallow caudal peduncle, caudal peduncle short, 5 4 (5.2 9 2)% SL, strongly compressed, depth subequal to orbital diameter Distance between middle of anus and base of anal fin slightly less than suborbital depth Body cavity extending to above origin of anal fin

Head acute, of moderate size, length 23 3 (23 3 31 6)% SL, width unknown (14 9 19 8)% SL and depth unknown (11 0 17 9)% SL, snout of moderate length 7 5 (6 5 9 6)% SL, not projecting in advance of upper jaw, rounded in dorsal view Nostrils small, located about two thirds to three quarters of the way from snout tip to eye, distance from nostril to orbital margin about equal to or greater than diameter of combined nostrils, nostrils positioned above horizontal through centre of eye, both with low tubular rim, posterior opening about half size of anterior, separated from it by raised skin flap Interorbital of moderate width, very slightly convex Eye of moderate size, orbital diameter 20 8 (16 8 28 5)% HL, unknown (0 91 1 68) times in interorbital space, unknown (1 46 4 71) times suborbital distance, circular, upper edge of eye adjacent to

Figure 7 *Pseudophycis barbata* A NMNZ P037124 450 mm SL Bay of Plenty east of north east point North Island New Zealand photograph C Struthers NMNZ   B BMNH 1863 1 15 38 holotype of *Pseudophycis barbata* 394 mm SL Victoria South Australia photograph © The Trustees of the Natural History Museum London

dorsal margin of head in lateral view Postorbital moderately long, 1.00 (0 52 1 21) times length of upper jaw Mouth large, terminal, upper jaw terminating at vertical through posterior margin of eye Jaw teeth caniniform, slightly curved, depressible, band of up to four or five irregular rows in upper jaw with distinct hiatus at symphysis, teeth in outer row more regularly arranged than in inner rows, band tapering near rear of jaw Teeth of lower jaw similar in form to those of upper jaw, band of two or three rows with broader patch on either side of symphysis, tapering to single, widely spaced row posteriorly, rows almost contiguous across symphysis Vomerine teeth absent Opercular bones strong, upper extremity of gill opening at horizontal through middle of eye, gill membranes continuous across isthmus Gill rakers on outer arch slender, moderately

short, unknown (about 0 6 0 8) times length of opposing gill filaments near angle, unknown (19 22) times in head length, slightly denticulate Chin barbel of moderate length, subconical 21 1 (16 5 25 3)% HL

Very small cycloid scales covering all of head and body except for branchiostegal membranes, surface of maxilla and premaxilla, lower lip and distal parts of fins, thick mucus covering obscuring scales and pores in freshly preserved material Most head pores tiny, following main cephalic sensory canals, row of slightly raised pores from nostrils to tip of snout and then posteriorly just above lower edge of suborbital, row of enlarged mandibular pores on underside of lower jaw Lateral line comprising widely spaced pores on short tubes arising from narrow scale less gap, anterior end

curved upwards slightly, then gradually descending to lateral midline below posterior 25% of second dorsal fin, remaining on lateral midline posteriorly

Membranes of first and second dorsal fins continuous at base, first dorsal originating distinctly behind vertical through pectoral fin base; anterior two thirds of second dorsal of uniform height, 7th to 9th ray from posterior end of fin longest, its height about 1 4 times length of 2nd ray at anterior end of fin, last ten or so rays progressively shorter, rays of both dorsal fins mostly unbranched, only last 13 to 16 rays, apart from last one to three, branched Fleshy, fine scale covered basal sheath on third or more of first dorsal and anterior portion of second dorsal fins, fin rays interconnected by membranes to tips, sheath gradually decreasing slightly in coverage and thickness posteriorly, encompassing about half of second dorsal fin near its insertion, sheath extending onto body for anterior third of combined dorsal fin base, broadest anteriorly, narrowing posteriorly Profile of anal fin like that of second dorsal fin, although less deep posteriorly, with comparable unbranched and branched rays Likewise, anal fin enclosed in broad fleshy sheath that is like that of dorsal fins, sheath also extending onto body for anterior third or less of fin Caudal fin distinctly rounded without obvious dorsoposterior and ventroposterior corners in adults, all but anterior most rays of similar length, base of fin covered by indistinct sheath with much smaller scales (sheath sharply demarcated from scales of caudal peduncle) Pectoral fin tip variably reaching not quite to, or past vertical through anal fin origin, sixth or seventh ray longest Pelvic fin inserted anterior to vertical through posterior edge of preopercle, outer two rays longer than inner rays, second ray longest, 13 3 (13 3 24 9)% SL, nearly twice length of subsequent ray, reaching vertical through first dorsal fin origin

Fresh colour. (Based on images of non type material, fig 7A) Medium to dark reddish brown above, extending ventrally to level of ventral portion of pectoral fin base, white below in smaller individuals, large individuals becoming brown ventrally and often much darker, lateral line not distinctively coloured Underside of head, jaws and barbel white, tinged with pink to orange, becoming more orange to brown in larger individuals, ventral margin of suborbital dusky to dark Dorsal and caudal fins of similar colour to brown of sides, anal fin pink or orange in smaller individuals, becoming brown like other median fins in large individuals, dorsal, caudal and anal fins with distinct broad to narrow black margin distally, margin on caudal fin broadest Pectoral fin orange to brown with faintly darker semi circular brown blotch basally, covering dorsal 80% of edge of fin proximally Pelvic fin rays white with pink to orange hue, becoming brownish in large individuals

Preserved colour. Head and body dusky to dark dusky, underside of head, belly and side adjacent to anal fin pale, especially in small specimens, extent of pale underside less in large individuals Dorsal, caudal and anal fins dusky to dark dusky, anal fin often less dark than dorsal and caudal, distal edges of dorsal, caudal and anal fins with distinctly dark margins, dark margin on caudal fin broad, pectoral fin broadly dusky basally, becoming pale toward outer margin Pelvic fin pale dusky

Etymology. The specific epithet *barbatus* is Latin for "bearded" in reference to the chin barbel, which is characteristic of this species, its congeners and many other members of the family

Distribution. Endemic to coastal waters of Australia and New Zealand from Rottnest Island, Western Australia (32° 01' S, 115° 30' E), to Port Stephens, New South Wales (32° 30' S, 152° 35' E), including all of Tasmania and around both the North and South Islands of New Zealand, reaching the Chatham Islands in the east (fig 3B) A demersal species on rocky bottom at 1 to at least 520 m Although found at considerable depths in New Zealand waters, this is a shallow reef dwelling species in southern Australia, where it shelters in caves and beneath overhangs during daylight hours, venturing out at night to feed

Remarks. *Pseudophycis barbata* has an overall darker colouration than its congeners, often with a reddish hue in fresh material, and distinct black margins to the dorsal, caudal and anal fins In particularly dark individuals, the basal portion of the pectoral fin is similarly dark but lacks the distinct black spot present in *P. bachus* and *P. palmata Pseudophycis barbata* is easily separable from *P. breviuscula* by the more numerous scales (16 22 vs 7 9) in a transverse row between the dorsal fin origin and lateral line

As mentioned above under Remarks for *P. palmata*, McCoy's (1878 29) treatment of *P. barbata*, the first published after Gunther's original description, was largely based on specimens of *P. palmata*, but the accompanying illustration is of a large specimen of *P. barbata* Although Ramsay's (1881) description of *Lotella grandis* is inadequate for a conclusive identification of the species, the lone type specimen (AMS I 696) is clearly *P. barbata* Early taxonomic confusion resulted in Steindachner (1901 509) reporting *P. barbata* from New Zealand as *L. grandis*, Norman (1937 55) speculating that *P. barbata* (as *Physiculus barbatus*) may be identical with *P. bachus*, and Graham (1938 399) and Habib (1975) treating it in New Zealand as *P. breviusculus* The last stems from our assumption that *P. breviusculus* does not occur in the waters of the South Island based on specimens examined and reliable identification records

Material examined Types Pseudophycis barbatus BMNH 1863 1 15 38 (394, holotype) Victoria, South Australia (fig 7a), *Lotella grandis* AMS I 696 (503, holotype) Wollongong, New South Wales

?*Austrophycis marginata* (nec Gunther, 1878) Cohen in Cohen et al , 1990 356 (taxonomy of *A megalops*)

Diagnosis. First dorsal fin with 8 10 rays, second dorsal fin with 44 52 rays, anal fin with 49 56 rays, total vertebrae 42 45, nostrils adjacent to anterior margin of orbit, interval between nostril and orbital margin less than diameter of combined nostrils, posterior nostril with raised anterior border but without tubular flap posteriorly; gill rakers of outer arch moderately short, those near angle much shorter than opposing gill filaments, caudal peduncle short 28 8 33 4% HL, chin barbel of moderate length, 23 4 30 5% HL, scales above lateral line in oblique series from base of first dorsal fin ray 7 9, oblique rows of scales intersecting with lateral line 77 93, pyloric caeca 7 8, caudal fin rounded without angular corners, the middle rays equal to or longer than the rays above and below, no distinct dark blotch at base of pectoral fin, underside of head, body and anal fin tan to brown, anal fin with fine black distal margin A small species reaching at least 151 mm SL

Description. (Values for non type specimens when different from type in parentheses, see Tables 2 4 for summary of selected meristic and comparative morphometric values) First dorsal fin 9 (8 10, rarely 8), first ray often minute; second dorsal fin 46 (44 52, rarely less than 46), anal fin 50 (49 56), pectoral fin 21 (20 23), pelvic fin 4 (4 5), caudal fin 26 (26 32, rarely 26), gill rakers 3 (2 3) + 8 (7 8) 9 12, lateral line pores not associated with individual scales, oblique scale rows intersecting with lateral line 93 (77 93), scales in oblique series above lateral line 7 (7 9), scales in oblique series below lateral line 23 (22 28, rarely 28), vertebrae 13 (11 14, rarely 11) + 31 (30 33) 42 45, rarely 42, pyloric caeca 7 8

Body of moderate depth, moderately compressed laterally (fig 8), greatest depth at or just in advance of anal fin origin 22 8 (20 6 23 3)% SL, tapering gradually from second dorsal fin origin to posterior portion of fin and then more steeply to shallow caudal peduncle, caudal peduncle short, 4 8 (5 7 8 5)% SL, strongly compressed, depth subequal to orbital diameter Distance between middle of anus and base of anal fin less than diameter of posterior nostril Body cavity extending to above origin of anal fin

Figure 8 *Pseudophycis breviuscula* A CSIRO H 4384-01 110 mm SL Albany Western Australia photograph compliments CSIRO Marine Research B BMNH 1855.9.19.1182 holotype of *Lota breviuscula* 152 mm SL Bay of Islands New Zealand photograph © The Trustees of the Natural History Museum London

Head acute, moderately short, length 25.8 (23.4 26.0)% SL, its width 16.6 (12.4 17.9)% SL and depth 12.1 (10.8 15.2)% SL, snout moderately short 5.9 (5.1 7.0)% SL, not projecting in advance of upper jaw, rounded in dorsal view. Nostrils small, located on posterior half of snout just in front of eye, distance from nostrils to orbital margin less than diameter of combined nostrils, nostrils positioned above horizontal through centre of eye, diameter of posterior opening about 1.5 diameter of anterior, separated from it by raised skin flap, posterior opening without tubular flap encircling posterior margin. Interorbital of moderate width, slightly convex. Eye of moderate size, orbital diameter 27.4 (24.7 35.7)% HL, 0.91 (0.53 1.10) times in interorbital space, 3.72 (2.20 5.78) times suborbital distance, circular, upper edge of eye just below dorsal margin of head in lateral view, skin covering eye unpigmented. Postorbital moderately long, 1.09 (0.97 1.50) times length of upper jaw. Mouth large, terminal, upper jaw terminating just posterior to vertical through posterior margin of eye. Jaw teeth small, caniniform, slightly curved, depressible, band of up to four or five irregular rows in upper jaw with narrow hiatus at symphysis, band tapering near rear

of jaw. Teeth of lower jaw similar in form to those of upper jaw, band of several rows with broader patch on either side of symphysis, tapering posteriorly, rows almost contiguous across symphysis. Vomerine teeth absent. Opercular bones strong, upper extremity of gill opening at horizontal through middle of eye, gill membranes continuous across isthmus. Gill rakers on outer arch club-shaped, moderately short, about 0.3 0.8 times length of opposing gill filaments at angle, 15 23 times in head, slightly denticulate. Chin barbel of moderate length, subconical 21.0 (19.6 30.5)% HL.

Moderately small cycloid scales covering all of head and body except for branchiostegal membranes, surface of maxilla and premaxilla, lower lip and distal parts of fins, very thick mucus covering obscuring scales and pores in freshly preserved material. Most head pores tiny, following main cephalic sensory canals, row of slightly raised pores extending from tip of snout posteriorly just above lower edge of suborbital, row of enlarged mandibular pores on underside of lower jaw. Lateral line comprising pores on tubes arising above upper end of gill opening, anterior end curved upwards slightly, then gradually descending to lateral midline below

posterior third of second dorsal fin, remaining on lateral midline posteriorly

Membranes of first and second dorsal fins continuous at base, first dorsal originating distinctly behind vertical through pectoral fin base; anterior two thirds of second dorsal of uniform height, 7th to 9th ray from posterior end of fin longest, its height about 1 2 times length of 2nd ray at anterior end of fin, last eight or so rays progressively shorter, rays of both dorsal fins mostly unbranched, only about last 14 or 15 rays, except last few, branched Fleshy basal sheath on base of first dorsal and anterior portion of second dorsal fins not especially prominent with scales apparently confined to basal margin of fin, fin rays interconnected by membranes to tips, sheath more obvious on body below much of combined dorsal fin base, broadest anteriorly, narrowing posteriorly Profile of anal fin similar to that of second dorsal fin, with comparable unbranched and branched rays Fleshy sheath on and below anal fin similar to that of dorsal fins Caudal fin rounded without distinct dorsoposterior and ventroposterior corners, posterior margin distinctly convex, all but anteriormost rays of similar length, base of fin covered by indistinct sheath (sheath demarcated from scales of caudal peduncle) Pectoral fin tip reaching past vertical through anal fin origin, seventh or eighth ray longest Pelvic fin inserted anterior to vertical through posterior edge of preopercle; outer two rays longer than inner rays, second ray longest, 17 6 (16 6 21 6)% SL, two to four times length of subsequent ray, reaching vertical through first dorsal fin origin

Fresh colour. (Based on images of non type material, fig 8B) Medium brown to pale brown above, paler below with white chest and belly in smaller individuals, bronze in larger individuals, lateral line not distinctive Underside of head and jaws brownish, ventral edge of suborbital darker brown, barbel white Dorsal, anal and caudal fins very pale brown in smaller individuals, darker in large individuals, fins with distinct broad to narrow black margin distally, more diffuse in large individuals Pectoral fin orange with very faint semi circular brown blotch basally Pelvic fin rays white with pink to orange hue

Preserved colour. Head, body and fins pale dusky to dusky, chest and belly very pale, ventral edge of suborbital darker, distal edges of dorsal, caudal and anal fin with diffuse darker margins

Etymology. The name *breviuscula* is Latin for "rather short", probably in reference to the relatively small maximum size of the species compared with others of the genus, although Richardson separated it from other New Zealand morids simply by fin counts

Distribution. Endemic to coastal waters of Australia and New Zealand, from Perth, Western Australia (32° 01' S, 115° 30' E), to Tweed Heads, New South Wales (28° 14' S, 153° 50' E), including all of Tasmania and around the North Island of New Zealand (fig 3C) A demersal reef dwelling species at 0 273 m, although most often encountered at less than 100 m on rocky and boulder reefs (Struthers et al in Roberts et al , 2016 864)

Remarks. P. breviuscula is the smallest of the four species in the genus, reaching less than half the maximum length of its

congeners. It also occurs in slightly warmer waters compared with the other three members of the genus, reaching well onto the northern New South Wales coast in eastern Australia and around New Zealand's North Island

Paulin (1983 94) provided a thorough synonymy of *P. breviuscula* from a New Zealand perspective but failed to mention *Austrophycis megalops* Ogilby, 1897, which was based on a specimen from New South Wales, Australia This omission was possibly due to the widespread uncertainty about the identity of Waite's shrivelled 65 mm type specimen Some authors regarded Ogilby's species as congeneric with Gunther's (1878 19) *A. marginatus* based on material from the south eastern Pacific and others thought the two were likely to be conspecific (Cohen in Cohen et al , 1990 356) Sazonov (2001 343) reported that he had examined the type specimen and found it to be *P. breviuscula* relegating the name *A. megalops* to synonymy with that species

Material examined Types Lota breviuscula BMNH 1855 9 19 1182 (152, holotype) Bay of Islands, New Zealand (fig 8a), *Austrophycis megalops* AMS I.3655 (65, holotype) Maroubra Bay, New South Wales, Australia, 33° 57' S, 151° 16' E, T Whitelegge, 1897 (after Sazonov, 2001 343, holotype, not re examined for this study)

Abstract

Wells, A. and St Clair, R.M. 2021. Review of the Australian endemic odontocerid genus *Barynema* and status of Australian *Marilia* (Trichoptera). *Memoirs of Museum Victoria* 80: 101–112

In this review of Australian Odontoceridae, we revise details of the two established species in the endemic genus *Barynema* Banks – *B. costatum* Banks and *B. australicum* Mosely – and describe six new congeners, *B. paradoxum* sp. nov., *B. lorien* sp. nov., *B. lobatum* sp. nov., *B. dilatum* sp. nov., *B. dolabratum* sp. nov. and *B. goomburra* sp. nov. For the only other odontocerid genus recorded for Australia, *Marilia* Muller, we discuss the present status of the three described species – *M. bola* Mosely, *M. aenigmata* Neboiss and *M. fusca* Kimmins – and outline our efforts and those of others to resolve problems of species delimitation based on morphology. We select a new replacement name for *Marilia fusca* and provide brief notes on the larvae of both genera.

Keywords

venation, CO1 data, distributions, homonym

Introduction

The family Odontoceridae is one of several groups among Australian Trichoptera, upon which Arturs Neboiss (late of Museums Victoria) made some preliminary studies but then set them aside. In 2003, he published a new Tasmanian species of *Marilia* Muller, 1878 (*M. aenigmata*), thus bringing to three the Australian species reported for this genus. *Barynema* Banks, 1939, the only other odontocerid genus recorded for Australia, is endemic, comprising two established species. Discrimination between adult males of these two *Barynema* species and a further six species, newly described here, is reasonably easy based on male genitalic features, augmented for some by thoracic features, but this is not so for discrimination between adult specimens referrable to *Marilia*.

The genus *Marilia* has almost a worldwide distribution. Features of the genus are discussed in detail in works by Oláh and Johanson (2010) and Yang et al. (2017). Oláh and Johanson (2010) found that "[m]any species have similar male genitalia, and it is difficult to differentiate all species by examining the phallic apparatus alone" (p. 73). Working with east Asian species, they advocated discrimination of species based on combined genitalic features and cephalic setal wart patterns.

The three species of *Marilia* described from Australia – *Marilia bola* Mosely, 1953, and *M. fusca* Kimmins, 1953 (both described in the work by Mosely and Kimmins, 1953), and *M. aenigmata* – all have very uniform male and female

genitalia. Differentiation of the first two appears, on paper, to be relatively simple. Males of *Marilia bola* have the eyes holoptic (almost touching the vertex) and a tuft of long setae on the anal lobe of the hind wing, whereas males of *M. fusca* have the eyes dichoptic (not approximated) and lack the tuft of setae on the wing. The female of *M. bola* was described and illustrated, but not the female of *M. fusca*. Neboiss, in describing the Tasmanian *M. aenigmata*, gave a small table of comparison of features of all three species, noting that *M. aenigmata* exceeds *M. bola* in size and, in comparison with *M. bola*, lacks Fork 3 in the female forewing and has hindwing Fork 1 sessile, not stalked (petiolate).

Confusing any simple separation of species, however, in preliminary studies on Australian *Marilia* specimens in the considerable Museums Victoria collection, Brian Armitage (in 1990) recognised two major sets among *Marilia* specimens from sites along the length of the Great Dividing Range, from central Victoria to far north eastern Queensland, and labelled specimens accordingly. He designated these *Marilia* Sp. A and *Marilia* Sp. B, based mainly on wing features. In several samples from a single site, he recognised both forms. Males of both sets have the compound eyes holoptic and, in their genitalic features, exhibit no clearly consistent differences. Females are inseparable on genitalic features. Both sexes of *Marilia* Sp. B have Fork 1 in the hind wing petiolate, and the associated females have forewing Fork 3 present. Thus, *Marilia* Sp. B could be *Marilia bola*.

Armitage's Sp. A has Fork 1 in the hindwing sessile and the associated females lack forewing Fork 3 It shares these wing features and genitalic characteristics with *M. fusca* and *M. aenigmata* However, the eyes of the type specimen of *M. fusca* as described by Kimmins (in the work by Mosely and Kimmins, 1953) are dichoptic, thus, *Marilia* sp A is not conspecific with *M. fusca* Or, conceivably, it could be if the situation is as Oláh and Johanson (2010) determined for their newly described South East Asian species *Marilia malickyi* that there is "[i]ntraspecific variation in the interocular distance" (p 74) Armitage's Sp. A does conform morphologically with *M. aenigmata*. The body size of mainland specimens varies considerably, with many being much smaller than the Tasmanian specimens

The only specimens in the available collections that concur completely with the description of *M. fusca* are in several small samples collected from streams in the Mount Spec State Forest (to the north of Townsville in north east Queensland) and a stream near Tully Surprisingly, no dichoptic males have been identified among samples from further south to the Sydney region or the Oxley Rivers region of New South Wales from whence the type and paratypes, respectively, were taken, nor further to the north in Queensland

None of this is particularly satisfactory and does not corroborate the equally unsatisfactory preliminary results from the limited patchy and geographically scattered CO1 data from adults and larvae that are available on the Biodiversity of Life Database (BOLD, http www boldsystems org) The BOLD data suggest there are at least eight species of *Marilia* in Australia, most with large genetic distances of at least 10% between them This is apparent from the very limited number of specimens available for genetic analysis More collecting and analysis will probably reveal further species Three specimens from north east Queensland, from localities from which specimens identified by Armitage as sp B were collected, have venation that differs from both *M. aenigmata* and *M. bola*

Similarly puzzling is the available information on larvae of Australian species of *Marilia* Larvae and pupae from the Yarra River at Reefton, Victoria, were described by Drecktrah (1990) as those of *M. fusca* He gave no indication of how the identification was made, and it is impossible to be certain from the anterior view if the pupal head illustrated by Drecktrah would have emerged as female or male, holoptic or dichoptic It now seems very unlikely that the larvae described by Drecktrah are *M. fusca* In 2004, Dean et al published a key for discrimination of late instar larvae of *Barynema* and *Marilia*, and separation of three species of *Marilia*, identified as *M. bola*, *M. fusca* and *M. aenigmata*, photographic images are given to illustrate diagnostic features used in the key *Marilia fusca* and *M. aenigmata* were separated in the key simply by geography, and the authors comment that their larvae are similar and may eventually be found to be the same species In recent collecting of *Marilia* larvae from New South Wales and Queensland, St Clair (unpublished) has noticed further small differences Identification of larvae of *Marilia* species is

therefore not possible until larvae can be associated with known adults All available specimens can be assigned to two larval types that align with the names given by Dean et al (2004) These are probably better labelled "*Marilia* larval sp 1" (was *bola*) and "*Marilia* larval sp 2" (was *fusca*) since such confusion is now recognised Further studies involving association of adults and close morphological examination of larvae are required

Marilia fusca is a junior secondary homonym of the name *Anisocentropus fuscus* Banks, 1905 (synonymised with *Marilia flexuosa* Ulmer, 1905, by Betten, 1934), so here we select a replacement name

Overall this is a confusing mix, probably only solved by a thorough and comprehensive combined morphological and molecular phylogenetic study For the present, it is not possible to assign Australian specimens of *Marilia* to species Thus, we can offer no further insight into Australian *Marilia*. The late Arturs Neboiss would understand

Material and Methods

Most of the material studied is in the collection of Museums Victoria, Melbourne (NMV) and bears the standard NMV registration number Genitalic specimens that were macerated and cleared by Neboiss are tagged with PT numbers and several others have WTH (Wet Tropics Heritage) numbers or BOLD identifications A small number of specimens are in the Australian National Insect Collection (ANIC), Canberra, or will be lodged in the Queensland Museum (QM) Images of types in the Natural History Museum, London (BMNH) were provided by Dr Ben Price Other images were taken at ANIC by AW and were prepared using a stereomicroscope linked to a Leica Application Suite (version 4 2) to integrate multiple images, some of the images are of cleared, others of intact, specimens Plates were prepared in Adobe Photoshop (version 12)

The terms applied to wings follow Mosely and Kimmins (1953), and the terms applied to genitalic structures follow Yang et al (2017), save for structures that in ventral view appear beside the phallus, for which we follow Mosely and Kimmins in using the term "upper penis cover" This latter structure could represent tergite X or the phallobase, but it appears to arise further ventrad than one would expect for the former and to be independent of the phallus, so probably is not homologous with the latter

Taxonomy

Marilia Müller

Marilia fusca Kimmins (in the work by Mosely and Kimmins), 1953 167, fig. 112

Marilia disjuncta nom nov , new replacement name for *Marilia fusca* Kimmins, preoccupied by *Anisocentropus fuscus* Banks, 1905, a junior synonym of *Marilia flexuosa* Ulmer, 1905

Barynema Banks

Figures 1 35

In their treatment of the Australian endemic genus *Barynema*, Mosely and Kimmins (1953) discussed its early placement in the family Calamoceratidae and their rationale for transferring the genus to the family Odontoceridae on the grounds that *Barynema* lacks the median cell in the forewing Adults of *Barynema* species are distinguished from Australian representatives of *Marilia* by having a pair of setose warts on the mesoscutum, whereas *Marilia* has two rows of setae, males of many specimens of *Marilia* have holoptic compound eyes, not seen in any *Barynema* Two species of *Barynema* – *B. australicum* Mosely, 1953, and *B. goomburra* sp nov, also have a pair of setate warts posteriorly on the mesoscutellum, a characteristic that appears to be absent in all other Odontoceridae. This could be considered a distinguishing feature at the genus level but given the very close similarity of other male and female features of species assigned to *Barynema*, we believe all eight species are appropriately referred to a single genus Similar variation in presence and absence of mesoscutal and mesoscutellar setal warts and their arrangement is seen in the closely related Philorheithridae (Neboiss, 1977)

In the inferior appendages of the males of some species of *Barynema* (e g. *B. costatum* and *B. australicum*), the harpago appears to be fused with the coxopodite (or lost?) In other species, a rather similar structure (when viewed laterally) appears to be simply an extension of the coxopodite that is probably homologous with the structure termed "subapicodorsal lobe of an inferior appendage" by Yang et al (2017, p 88) The socketed harpago forms a smaller, but morphologically similar, structure (e g *B. lobatum* sp nov) or is reduced to a small triangular (*B. dilatum* sp nov) or subquadrate (*B. dolabratum* sp nov) lobe laterad of the extended coxopodite, it usually bears an area of short peg like black setae A similar situation appears to occur in the east Asian species *Psilotreta malickyi* Oláh and Johanson, 2010, although in that species the reduced harpago is a mesal structure In females of *Barynema*, the apical lobes are stout structures on abdominal segment X, while in *Marilia* they are absent or fused with tergite X

Here, new records and images are given for each of the two established species of *Barynema B. costatum* from Victoria and *B. australicum* from north eastern New South Wales Thoracic and female genitalic features are described and illustrated for these species In addition, six new species are described, based on male and female thoracic and genitalic features, and a key is provided for the genus The genus has been collected along the Great Dividing Range of eastern Australia but has not been recorded further west, in the south, the genus is not recorded from west of the central ranges of Victoria or from Tasmania Genetic data from BOLD suggest that additional species are present in Australia

Larvae of a few species can be associated with the adult using the CO1 barcode The larvae show subtle differences that may enable species separation, but this is best left until more species are associated The larval and pupal descriptions of *Barynema costatum* by Cartwright and Dean (1987) may not be that species and may not be adequate to separate larvae of related species

Key to males of *Barynema* Banks.

1. Mesoscutellum subcircular to rectangular, bearing small paired setate warts separate from each other and close to posterior margin (figs 29, 33) 2

-   Mesoscutellum ovoid, with large paired setate warts fused and covering most of mesoscutellum (fig 5)   3

2. Inferior appendages, each with harpago in ventral view bearing abbreviated area of short stout black peg like setae subapicomesally, coxopodite with short mesal lobe bearing similar, but tapered, setae (fig 32)
B. australicum Mosely

-   Inferior appendages, each with harpago in ventral view bearing elongate area of short stout black peg like setae subapicomesally; coxopodite without mesal lobe (fig 35)
B. goomburra sp nov

3   Inferior appendages, each with brush of short, stout black setae on harpago subapicomesal, elongate, extending along distal half of mesal margin (figs 3, 6)
B. costatum Banks

-   Inferior appendages, each with brush of short stout black setae on harpago apical and rounded, not elongate (figs 9, 13, 18, 21, 25)   4

4. Lobes of upper penis cover in ventral view expanded apicolaterally (figs 21, 25)   5

-   Lobes of upper penis cover in ventral view tapered, acuminate to rounded apically, but not expanded apicolaterally (figs 9, 13, 15, 18)   6

5   Apicolateral lobes of upper penis cover in ventral view rounded (fig 21) ... ... *B. dilatum* sp nov

-   Apicolateral lobes of upper penis cover in ventral view sharply triangular, pick shaped (fig 25)
B. dolabratum sp nov

6. Inferior appendages, each with coxopodite in ventral view about 2 times as long as wide (figs 13, 15)
B. lorien sp nov

-   Inferior appendages each with coxopodite in ventral view subquadrate (figs 9, 18)   7

7   Coxopodites in ventral view, each with mesal margin rounded (fig 18)   *B. lobatum* sp nov

-   Coxopodites in ventral view, each with mesal margin angled obliquely from base (fig 9) *B. paradoxum* sp. nov

Barynema costatum Banks

Figures 1, 3 8

Barynema costatum Banks, 1939 484, figs 43, 51, 54

Material examined Holotype male, Victoria, Mount Donna Buang, 6 7 December, Darlington (ANIC, ex CZM, dry on a pin) Victoria 1 male (dissected), Cement Creek near Warburton, 4 xi 1972, P Zwick (NMV Tri 26514, PT 1389) Victoria 1 adult female, same data (NMV Tri 26517, PT 1890), 1 male (pharate adult, dissected), small trib Snobs Creek, Snobs Road crossing bridge, 11 6 km u s Eildon Road, 31 x 1981, J Dean (NMV Tri 26506), 1 female (reared), Back Creek, 1 km NE of Noorinbee, 13 x 1982, A Bolton, reared (NMV Tri 26518)

Diagnosis Males, when freshly caught or dried, have on the black forewing a band of white and golden hairs angled across the wing at about 3 5 length and a streak of golden scales and hairs between A1 and Cu2, on the inferior appendages, a rather elongate hairbrush like cluster of short and blunt black setae line the inner subapical or apical region of the harpago, features that distinguish them from *B. paradoxum* sp nov with similar black wings, but with the distal band of hair on the forewing wing only slightly curved and the harpago with a rounded cluster of short black setae apically, in ventral view, the basal section of the coxopodite is broadly subrectangular in *B. costatum*, but more rounded in *B. paradoxum*, and the upper penis cover with each lobe expanded laterally toward the apex, rather than tapered or rounded

Description (revised after Mosely and Kimmins, 1953)

Mesothorax with scutellum subquadrate, without mesoscutellar setate warts

Male Body and wings (figs 1, 3, 4) black, forewings each with gold band along proximal section of A1 and white band across vein anastomoses at about 3 5 wing length, length of each forewing 9 5 mm (n 1) Mesoscutellum ovoid, without setate warts Abdominal sternite VII bearing median subquadrate lobe Genitalia Pre anal appendages in dorsal view stoutly conical, about length of inferior appendages, upper penis cover elongate, wrapped lateroventrad of phallus, flared and widest towards apex, inferior appendages in ventral view with coxopodite stout, subquadrate basally, harpago in ventral view slender, with elongate apicomesal brush of sharp, stout black setae lining distal half, giving hairbrush like appearance

Female Terminalia Distal abdomen bearing pair of short, stout, apically truncate apical lobes, striated plates ventrally on segment IX

Distribution. Found in central and eastern Victoria

Remarks Very few specimens of *B. costatum* have been collected many of the specimens previously identified as *B. costatum* are assigned here to the new species *Barynema paradoxum* sp nov BOLD data groups the two, with only a short distance between them One of the few confirmed *B. costatum* specimens is a pharate pupa from a tributary of Snobs Creek on the north western edge of the Great Dividing Range in central Victoria, images of which are included here (figs 5 8), particularly to show the form of the mesoscutellum that is obscured by the pin on the dried type

Barynema paradoxum sp. nov.

Diagnosis Males of *Barynema paradoxum* resemble those of *B. costatum* in having distinctive black wings with a median white band across the area of vein anastomoses and a band of bright yellow hairs between veins Cu2 and A1 But in *B. paradoxum*, the white band is slightly curved, not angled, and the area of golden setae is smaller. Like *B. costatum*, *B. paradoxum* shares with *B. dilatum* sp nov., *B. lorien* sp nov and *B. dolabratum* sp nov the absence of setate warts on the mesoscutellum and, as with those three species, the male of this new species has a rounded club of short, stout black setae apically on the distal extremity of each inferior appendage, not an elongate brush as in *B. costatum* Together with *B. lorien*

Figures 1–8 *Barynema* species. 1, 3, 4 *Barynema costatum* Banks holotype male. 1 body and wings dorsal. 3, 4 genitalia ventral, and lateral respectively. 2 *B. paradoxum* sp. nov. New South Wales Upper Kangaroo Valley body and wings dorsal. 5–8 *B. costatum* male Victoria tributary of Snobs Creek NMV TRI 27406. 5 mesothorax dorsal. 6–8 genitalia ventral, lateral, and dorsal, respectively. Abbreviations cox. coxopodite. har. harpago. ph. phallus. pre. app. preanal appendages. up. p. upper penis cover.

and *B. lobatum* sp. nov., *B. paradoxum* has the ventrolateral lobes of the upper penis cover tapered apically, rather than expanded. *Barynema paradoxum* is characterised by the coxopodite of each male inferior appendage subquadrate, not longer than wide in ventral view and not produced to form a rounded lobe at its apicomesal angle.

Description. Mesothorax without mesoscutellar setae warts. Body and wings black, each forewing with slightly curved band of white setae across vein anastomoses.

Male. Length of each forewing 6.2–9.7 mm (n = 10). Abdominal segment VII bearing small, sharp, sclerotised median spur. Genitalia. Pre-anal appendages stout, apices
Figures 9–17. *Barynema* species. 9–12 *B. paradoxum* sp. nov. holotype. New South Wales. Nowra. NMV TRI 27118. PT 1646. 9–11 male genitalia ventral, lateral, and dorsal, respectively. 12 female. NMV TRI 27061 PT 1564. genitalia ventral and lateral, respectively. 15–16 paratype male. Queensland. Lamington National Park. NMV TRI 27061. genitalia ventral and lateral, respectively. 17 paratype female. NMV TRI 27061 terminalia ventral.

Abbreviations ap. lob. = apical lobe. cox = coxopodite. har = harpago. ph = phallus. pre app = pre anal appendages. up p = upper penis cover

narrowly rounded in dorsal view, lobes of upper penis cover in ventral view tapered to acuminate apices, inferior appendages, each with coxopodite in ventral view stout, subquadrate basally, harpago about length of coxopodite, slender with a cluster of short, bristle like dark setae on rounded club shaped apex

Female Length of each forewing 9 0 mm (n 1) Terminalia Distal abdomen bearing pair of short apical lobes, stout basally, rounded laterally and tapered to rounded apices, striated plates ventrally on segment IX

Distribution Widespread in eastern New South Wales, extending into far eastern Victoria, possibly overlapping with *B. costatum*

Etymology Named for the past confusion over this species, and the paradox presented by the variability in male genitalic structures Most specimens were identified previously as *B. costatum*

Barynema lorien sp. nov.

Material examined Holotype male, New South Wales, Lansdowne via Taree, 29 ix 1985, G W Williams (NMV TRI 27071, PT 1564)

Paratypes Queensland 2 males, 1 female, [Lamington] National Park, 1 xi 1954, T F Woodward (NMV TRI 27060), 1 male, Lamington National Park, 15 xi 1955, Yeo (NMV TRI 27069), 1 male (reared from pupa), Tamborine Mountain, iii 1962, K Korboot (NMV TRI 27068), 1 female (reared from pupa), same data (NMV TRI 27067), 3 males, 1 female, Lamington National Park, xi 1982, T Hinger (NMV TRI 27061), 1 male, Lamington National Park, xi 1982, G Theischinger (NMV TRI 27065)

Other material New South Wales 1 male 1 female, Wentworth Falls, 22 xi 1960, C N Smithers (NMV TRI 27059), 1 male, same data (NMV TRI 27070), 1 male, [Barrington Tops State Forest], Manning River, Pheasant Creek Road, 3 xii 2007, A Glaister, J Dean and R St Clair (NMV TRI 54568, JOS 237)

Diagnosis Resembling *B. paradoxum*, *B. costatum*, and *B. lobatum* sp nov in having males with the pre anal appendages stout, apically rounded The male differs from that of *B. costatum* in having each inferior appendage terminating in a small rounded area of short black setae, not an elongate brush It is distinguished from *B. costatum* by having the lobes of the upper penis cover in ventral view acute apically, not flared distally as in *B. costatum*, and is distinguished from *B. paradoxum* by having the basal region of each inferior appendage subrectangular, not subquadrate, and from *B. lobatum* sp nov which has the mesal angle more strongly produced, rounded Females resemble those of *B. lobatum*, having the apical lobes short, stout, and stepped (obliquely truncate)

Description Mesothorax without mesoscutellar setate warts

Male Length of each forewing 6 8 7 5 mm (n 4) Abdomen with small sharply pointed spur medially on sternite VII Genitalia Pre anal appendages stout, rounded apically Upper penis cover forming pair of elongate lobes of

more or less uniform width for most of length, tapered slightly to apex Inferior appendages each with coxopodite basally long, subrectangular to ovoid in ventral view, without any tufts of setae or mesal lobes, harpago slender at base, slightly dilated distally, with round pad of short, stout black setae apically

Female Length of each forewing 8.3 9 6 mm (n 3) Terminalia Apical lobes, slightly stepped toward rounded apices

Distribution Found from eastern New South Wales, from the Blue Mountains to the west of Sydney to south eastern Queensland

Etymology Named after the Lorien Wildlife Refuge and Conservation Area near Lansdowne, New South Wales.

Barynema lobatum sp. nov.

http zoobank org urn lsid zoobank org act:5985E223 FC68 48B4 A1C4 19D51BD5F0C2

Figures 18 20

Material examined *Holotype* male, Queensland, Montville, Bon Accord Falls, 27 ix 1955, A N Burns (NMV Tri 27064)

Paratypes Queensland 3 male, 1 female, Montville, Bon Accord Falls, 29 ix 1955 A. N Burns (NMV TRI 27063), 1 male, same data (NMV Tri 27066), 1 male, south east Queensland, Stony Creek, Conondale Range, 10 viii 1988, S Bunn (NMV Tri 27120)

Diagnosis In most features, *B lobatum* sp. nov. resembles *B. lorien* sp nov but alone among congeners, this species has the apicomesal angle of the otherwise subquadrate coxopodite of the inferior appendages produced and rounded distally, the pre anal appendages are tapered distally, and a small rounded mesal process occurs on sternite VII The female is indistinguishable from those of *B. lorien*, both having stepped (obliquely truncate) apical lobes

Description Thorax with mesoscutellum almost subquadrate, pale, margin dark, lacking setate warts

Male Length of each forewing 5 2 7.2 mm (n 5) Sternite VII with small, apically rounded median tab Genitalia Pre anal appendages stout in dorsal view, tapered to rounded apices, in lateral view almost same width throughout, apically rounded Lobes of upper penis cover in ventral view constricted distally to form sharp tips, in lateral view stout, rounded apically Inferior appendages each with coxopodite in ventral view stout, apicomesal angle slightly produced, rounded, harpago narrow near base, cluster of short, dark, bristle like setae apically

Female Length of each forewing 8 6 mm (n 1) Terminalia Distal abdomen bearing pair of apical lobes, stout basally, narrowed laterally, and produced to rounded apex

Distribution Known only from north of Brisbane in the Sunshine Coast region of south eastern Queensland

Etymology. Named for the expanded apicomesal angles of the inferior appendages

Barynema dilatum **sp. nov.**

Other material North Queensland 3 females, upper Mulgrave River via Gordonvale, 29 30 April 1970, S R Curtis (NMV WTH 0786), 5 male, same data (WTH 2654), 1 female, Lock Davies Creek Road, Lamb Range, Mareeba District, 10 November 1974, M S Moulds (WTH 0437 PT 2028), 1 female, upper Freshwater Creek, Whitfield Range, Cairns, 24 August 1974, MV light, MS Moulds (WTH 0615), 1 male, same data (NMV WTH 0603), 1 male, same data (NMV WTH 0604), 1 male, upper Freshwater Creek, Whitfield Range, near Cairns, 15 December 1974, MS Moulds (NMV WTH 0606), 1 male, 1 male, same data (NMV WTH 0605), 1 male, same data (NMV WTH 0607), 2 females, same data (NMV WTH 0614), 1 male, the Crater, near Herberton, 18 December 1974, M S Moulds (NMV WTH 0602), 1 female, Mareeba, Davies Creek Road, 21 January 1976, Walford Huggins (NMV WTH 0616), 1 male, State Forest, 24 km along Goldsborough Road near Gordonvale, 27 xii 1980, M S and B J Moulds (NMV WTH 1350), 1 male, Behana Gorge, Cairns, 16 November 1982, T Hinger, 17° 11' S 145° 50' E (NMV WTH 0608), 2 females, same data (NMV WTH 0609), 1 male, Mossman Gorge, Daintree National Park, 17 November 1988, MV lt, K Walker (NMV WTH 0598), 1 male, river on Lake Morris Road, Cairns, 3 v 2011, 16 9412 145 71762 (NMV EPAVT122), 2 males, 5 females, river on Lake Morris Road, Cairns, 16 9412 145 71762, 3 v 2011, J Mynott and M Shackleton (NMV Tri 54557), 1 male, small creek beside Josephine Falls, M Shackleton and J Mynott, 6 v 2011 (NMV Tri 54559), 1 male, 1 female, Josephine Falls, 17 4338 145 8630, Shackleton and Mynott 110506 7, 6 v 2011 (NMV Tri 54558), 3 males, Dunn? Creek at Bridge 11, Kirrama Range Rd, ~14 km from national park sign, 18 2138 S 145 7982 E, 24 x 2017, D Cartwright and R St Clair, 1 male, Mulgrave Road, Goldsborough Valley Campsite, Wooroornoonan National Park, 17 2374 S 145 7733 E, 26 x 2017 (NMV JOS 451), 1 male, Python Creek in Tully Gorge Road, ~52 km NW of Tully, 17 7662 S 145 5895 E, 2 November 2017, D Cartwright and R St Clair (QM JOS 448)

Diagnosis The male of *Barynema dilatum* closely resembles that of *B. dolabratum* sp nov. in having the inferior appendages each with the harpago reduced to a small apically setose ventral lobe and the coxopodite in lateral view produced and curved ventrad distally In *B. dolabratum*, the upper penis cover in ventral view appears to form two lobes apically, with the ventral lobe expanded and rounded laterally, in contrast with *B dolabratum*, which has the upper penis cover in ventral view pick shaped apically

Description Mesothorax with mesoscutellum shield shaped, without setate warts, fresh adult males with body and wings dark except white area at anastomosis on wings

Male Length of each forewing 9 3 10 3 mm (n 10) Sternite VII without median tab or spur Genitalia Pre anal appendages in dorsal view broadest at about midpoint, constricted towards base Upper penis cover distally bilobed, dorsal lobe tapered apically in ventral view, rounded in lateral view, ventral lobe expanded and rounded laterally towards apex Inferior appendages each with coxopodite base short, stout, produced to form a dorsal lobe with slender neck before slightly dilated apex bearing short stubby black setae, harpago short, rod shaped, bearing dense brush of short black setae apically

Female Length of each forewing 11 8 17 7 mm (n 10) Terminalia Apical lobes conical, tapered to darkly sclerotised apices

Distribution From north eastern Queensland, west of Tully to the Cairns district

Etymology The name is derived from the Latin *dilato*, to extend, for the lateral swellings on the upper penis cover lobes

Barynema dolabratum **sp. nov.**

http zoobank org urn lsid zoobank org act 70CBA5A9 B547- 4657 9FF7 F5D89AA BF20F

Figures 25, 26

Material examined *Holotype* male, north Queensland, Gap Creek, 10 ii 1982, M S Moulds (NMV WTH 0599, PT-1176)

Paratypes North Queensland 1 male, Gap Creek, Mount Finlayson Range, S of Cooktown, 25 November 1974, M S Moulds (NMV WTH 0601), 1 male, Gap Creek, 10 February 1982, M S Moulds (NMV WTH 0600), 1 male, Oliver Creek on Bloomfield Road, 8 km S of Cape Tribulation, 16 1377 S 145 4408 E, 29 x 2017, D Cartwright and R St Clair (QM), 1 male, data as above, D Cartwright and R St Clair, NMV (JOS 452)

Diagnosis This species, known only from males, closely resembles that of *B. dilatum*, but is distinguished by the slightly smaller body, darker body, mesoscutal setate warts elongate ovoid, and the sharp, pick shaped form of the upper penis cover lobes in ventral view

Description Mesothorax with mesoscutellum shield shaped, without setate warts

Male Length of each forewing 9 0 10 6 mm (n 5) Small white area around lower part of wing at anastomosis Sternite VII without median spur or tab Genitalia Pre anal appendages stout, apically rounded in ventral view Upper penis cover lobes produced distally, pick shaped apicolaterally in ventral view, in lateral view triangular apico dorsally Inferior appendages each with coxopodite broad at base, in lateral view produced in slender, curved dorsal lobe bearing cluster of stubby black setae apically, harpago forming short apically truncate lobe bearing stout peg like black setae at tip

Female Unknown

Distribution Collected from Cape York, Queensland, from the two sites to the north of Cairns and south of Cooktown

Etymology From the Latin *dolabratus*, meaning pick shaped for the appearance of the upper penis cover lobes

Barynema australicum Mosely

Barynema australicum Mosely, in Mosely and Kimmins, 1953 162, figs 108, 109

Figures 27 32

Material examined Holotype. male, New South Wales, Ebor, 5 i 1916, R.J Tillyard, (BMNH) [head and abdomen mounted in balsam, images courtesy B Price, BMNH]

New South Wales 1 female, Wilson River Reserve near Bellangry, 5 xii 1986, G Theischinger (NMV TRI 26493), 1 male, Coomboodja Creek, Washford National Park, 29° 16' S 152° 22' E, 5 i 1986, Theischinger (NMV Tri 27119, PT 1655), 2 females, same data (NMV Tri 27116), 1 male ,1 female, "Cockerawo Creek", 23 km WNN Bellangry, 8 xii 1986, 730 m, G Theischinger (NMV TRI 26505), 19 males 1 female, Orara West State Forest, Tuckers Knob, 29° 41' S 152° 48' E, 27 xi 1990, G Theischinger (NMV TRI 27117), 1 male, Manning River, Pheasant Creek Road, A Glaister, J Dean and R St Clair, 3 xii 2007, 31° 53' S 151° 29' E (NMV TRI 54569, JOS 238), 1 male, Never Never River, Whitneys Road, 30 33001S 152 86222E, 10 xi 2010, 10110 5, MS 747 [M Shackleton] (NMV TRI 54570, JOS 108)

Diagnosis Distinguished from most other species of *Barynema* by having a pair of setate warts on the mesoscutellum, a feature shared with *B. goomburra* sp nov , from which it differs by having male genitalia in ventral view with the coxopodite of each inferior appendage subquadrate, and in both ventral and lateral views the harpago with a short, slender basal portion before the swollen terminal section that bears a broader hairbrush shaped area of short blunt black setae, rather than an elongate toothbrush shaped region as in *B. goomburra* sp nov.

Description Male Length of each forewing 6 4 7 8 mm (n – 10) Sternite VII bearing apically rounded median tab Genitalia see Mosely and Kimmins, 1953 162)

Female Length of each forewing 8 4 10 mm (n – 3) Terminalia Apical lobes on abdominal segment X short, broad, almost quadrate

Distribution. Found in north east New South Wales, in the Barrington Tops Wauchope and mid north coast regions

Remarks Two specimens among those that have been sequenced for the BOLD project can be referred to *B. australicum* Each appears in a different cluster on the current BOLD Taxon Identification Tree This is due to either contamination of the CO1 gene or the presence of sibling species Several more specimens are required before this can be resolved This species, together with specimens here referred to *B. dilatum* sp nov., show no presently resolvable relationships

Barynema goomburra sp. nov.

http zoobank org urn lsid zoobank org act:3B854FDD 8AFB 4F71 903C DFF0AFFF26FF

Figures 33 35

Material examined Holotype. male, Queensland, Goomburra State Forest, N E of Warwick, 28° 03' S 152° 07' E, 20 i 1986, G. Theischinger (NMV TRI 27112)

Paratypes New South Wales: 1 male, 4 females, Styx River, Hyatt Flat, 8 xii 1998, G Theischinger (ANIC)

Diagnosis Adults of this species closely resemble those of *B. australicum* in having a pair of setose warts on the mesoscutellum, the males of both species have a brush of short, blunt black setae terminally on each harpago and, in lateral view, the pre anal appendages are broad based and gradually tapered distally The male of *B. goomburra* is characterised by having the inferior appendages narrower than those of *B australicum* and the coxopodites lacking apicomesal clusters of setae that are present in *B australicum* The male of *B. goomburra* resembles that of *B. costatum* with the harpago bearing an elongate and narrow brush of stout black setae occupying almost its entire inner distal margin, but differs from *B costatum* in that *B goomburra* has a subcircular to rectangular mesoscutellum bearing small paired setate warts separate from each other and close to the posterior margin, whereas the mesoscutellum of *B costatum* is ovoid and with large paired setate warts fused and covering most of the mesoscutellum

Description Mesothorax with mesoscutellum bearing pair of setate warts close to distal margin

Male Length of each forewing 6 5 7 2 mm (n   2) Abdominal segment VII bearing stoutly rounded midventral tab Genitalia Pre anal appendages in lateral view elongate triangular, upper penis cover in ventral view forming pair of short, stout, apically expanded structures, inferior appendages in ventral view each with coxopodite about equal width throughout length, without apicomesal brush of setae, harpago not clearly delineated, with somewhat stout, short, blunt black setae lining entire mesal side, giving toothbrush like appearance

Female Length of each forewing 8 0 9 6 mm (n – 4) Terminalia Apical lobes broad based, arising close to each other, then tapered to narrowly rounded apices

Distribution Collected from just north of the New South Wales Queensland border, and from the Styx River in the Northern Tablelands area of New South Wales
Remarks No specimens recognisable as *B. goomburra* are among material for which molecular (CO1) data are available at present

Etymology Named for the holotype locality

Abstract   McCallum, A W., Ahyong, S T and Andreakis, N 2021 New species of squat lobsters of the genus *Munida* from Australia. *Memoirs of Museum Victoria* 80 113 152

This study reports on new squat lobsters of the genus *Munida* collected during recent surveys of Australia's continental margins We report on 33 species of *Munida* including seven new species and 14 new range extensions for Australia. More than 500 specimens were collected, mostly from the western continental margin of Australia, but also including a new species from deep water (˃2000 m) off Tasmania We provide new data on the colour patterns of some species and include molecular data from two mitochondrial markers (16S rRNA and COI) to support the taxonomic status of the new species

Introduction

Australia has a vast marine realm, the third largest jurisdiction in the world, encompassing tropical and temperate biomes and connected to the highly biodiverse Indo West Pacific region Over the last decade, efforts to document the biodiversity of Australia's deep seafloor habitats have grown, as a system of Marine National Parks were established and monitored Sampling of Australia's deep seafloor has revealed a high proportion of new species and significant range extensions, but most of these records await detailed taxonomic description

Squat lobsters (Chirostyloidea and Galatheoidea) are among the most diverse groups of decapod crustaceans in deep waters, and there have been intensive efforts to describe and revise species and higher taxa from the group (Macpherson and Baba, 2011) This has been assisted by the availability of taxonomic resources such as synoptic works (e g Baba, 2005, Baba et al , 2008) and keys (Taylor and Poore, 2010) In addition, molecular based approaches are helping to identify overlooked species that show only subtle morphological differences (Poore and Andreakis, 2012)

Munida is one of the largest genera of squat lobsters, currently comprising 297 species (WoRMS, 2021) The most recent major taxonomic study of *Munida* in Australia recorded 19 species (Ahyong and Poore, 2004) Additional records have since been added (e g Ahyong, 2007, Baba, 2005, Poore et al , 2008), so, to date, 32 species of *Munida* have been documented from Australia

Here, we report the specimens of *Munida* collected during several deep water surveys from 2005 to 2015, including surveys of the continental margin of Western Australia, the Great Australian Bight, Tasmanian seamounts, and the eastern Australian continental margins and abyss We describe and illustrate new species and record new occurrences of previously described taxa The synonymies for each species are restricted to papers published after the compilation of Baba et al (2008) Where available, we include molecular data from two mitochondrial markers (16S and COI) to support the taxonomic status of the species

Materials and methods

Sampling

Specimens were collected using beam trawls and epibenthic sleds in surveys aboard the FRV *Southern Surveyor* of the south western continental margin of Australia (SS10 2005) and north western continental margin (SS05 2007); and surveys aboard the RV *Investigator* of the Great Australian Bight (IN2015 C01 042) and the continental margin and abyss of eastern Australia (IN2017 V03) A small number of specimens were collected from south west Tasmania (TT 01 2008) using the remotely operated vehicle Jason aboard the RV *Thomas G Thompson* Specimens collected from well sampled sites on Tasmanian seamounts (SS01 2008, SS02 2007) were reviewed and represent well known species previously reported for the area, they are not redescribed herein

Morphological methods

Specimen measurements in *Material examined* refer to postorbital carapace length (pcl), measured dorsally from the base of the rostrum (situatued at the level of the orbit) to the mid posterior margin of the carapace, and where the rostrum is intact, carapace length (cl) is measured from the rostral apex to the mid posterior margin of the carapace The angle of the frontal margin from the midline is measured as the angle of the intersection between an imaginary line along the frontal margin and the median axis Thus, a transverse margin corresponds to an angle of 90° The lengths of articles of the cheliped are measured along the dorsal margin and those of ambulatory legs and maxilliped 3 are measured along the extensor margin and exclude spines Abbreviations used are Mxp3, maxilliped 3, P1, pereopod 1, P2 4, pereopods 2 4, M, male, F, female, ovig , ovigerous

Specimens are deposited in the collections of Museums Victoria, Melbourne (NMV), the Western Australian Museum (WAM), the Australian Museum, Sydney (AM), Muséum national d'Histoire naturelle, Paris (MNHN) and the South Australian Museum, Adelaide (SAM) Other abbreviations WA, Western Australia, acq refers to the Commonwealth Scientific and Industrial Research Organisation (CSIRO) acquisition number allocated to the specimen on board the vessel at the time of collection

Molecular analysis

Material collected from south western Australia (SS10 2005), being mostly preserved in formalin, was not sequenced

Total DNA was extracted from 50–100 mg of abdominal tissue or pereopod of the target specimen preserved in ethanol following the salt based extraction procedure described by Aljanabi and Martinez (1997) with minor modifications The partial mitochondrial cytochrome oxidase subunit I (COI) and 16S rDNA gene (16S fragment 2) were polymerase chain reaction (PCR) amplified following primer combinations, reaction conditions and thermal cycling profiles established previously (Cabezas et al , 2012) Quantity and length of the PCR products were examined by 1% gel electrophoresis against known DNA standards PCR reactions were sent to Macrogen Inc. (Korea, www.macrogen.com) for purification and direct sequencing in both directions. Electropherograms were assembled in Sequencher v4 9 and sequences were initially aligned in Bioedit v7 0 9 (Hall, 1999) together with 16S and COI sequences from previous works (Cabezas et al , 2009, 2011, Machordom and Macpherson, 2004, Macpherson and Machordom, 2005, Rodríguez Flores et al , 2019) Final alignments of each of the loci were performed using MAFFT (Katoh et al , 2002) Uncorrected divergences (p) were calculated using MEGA 10 04 (Kumar et al , 2018) GenBank accession numbers for the new sequences are given in Table 1 We have not provided the divergence values among all pairs of closely related species because in the genus *Munida* the amount of molecular data is still scarce (excluding the present paper, the sequences of only 72 species are available) Nevertheless, when the molecular data from a new species and its morphological closest relative are available, we have included the divergence values in the *Remarks*

Paratypes (all Western Australia) NMV J55036, 6 ovigerous females (cl 18 9 mm, pcl 11 2 mm to cl 25 9 mm, pcl 15 7 mm), 6 females (cl 14 0 mm, pcl 8 1 mm to cl 19 0 mm, pcl 12 5 mm), 10 males (cl 15.0 mm, pcl 8 9 mm to cl 22 8 mm, pcl 14 6 mm), collected with holotype, NMV J55262, 1 ovigerous female (cl 27 5 mm, pcl 18 3 mm), 1 female (cl 14 5 mm, pcl 8 4 mm), Barrow L1 transect, 20° 59 412' S, 114° 07 896' E to 20° 59 13' S, 114° 08 394' E, 700 m, SS05 2007 1, 9 June 2007, NMV J55279, 1 specimen, Mermaid L24 transect, 16° 44 286' S, 119° 15 042' E to 16° 43 794' S, 119° 15 48' E, 693 698 m, SS05 2007 70, 17 June 2007, WAM C78557, 1 male (cl 22 6 mm, pcl 13 0 mm), Ningaloo South, 22° 03 57' S, 113° 43.74' E to 22° 04 026' S, 113° 43 26' E, 658 754 m, SS10 2005 149, 10 December 2005

Description. Carapace Length and width subequal, widest at midlength. Dorsal surface with main transverse ridges mostly uninterrupted, without secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae Gastric region with large pair of epigastric spines behind supraocular spines and 2 or 3 pairs of small epigastric spines, without median row of spines behind rostrum Hepatic region granular, parahepatic spine present Anterior part of branchial region between cervical groove and postcervical groove with 1 or 2 ridges and sometimes 1or 2 short striae, postcervical spine present, posterior part of branchial region with 5 transverse ridges (excluding posterodorsal ridge) Cardiac region with 3 main transverse ridges Intestinal region with 2 lateral striae, posterodorsal ridge distinct, without secondary stria Frontal margin inclined posteriorly at 110° from midline Lateral margin slightly convex, anterolateral spines parallel, directed slightly upwards, reaching sinus between rostrum and supraocular spine, hepatic marginal spine anterior to cervical groove, much shorter than anterolateral spine, branchial margin with 4, occasionally 5, spines (additional third spine small) Rostrum spiniform, curving dorsally, 0 6 0 7 × pcl, supraocular spine length 0 3 length × rostrum length Epistomial ridge straight, ending at antennal gland, mesial protuberance distinct

Thoracic sternum Median length of sternal plastron (sternites 4 7) 0 6 × width of sternite 7 Thoracic sternites suface smooth, sternites 4 with few striae Sternite 3 0 5 × width of sternite 4 Sternite 4 anterior margin subtriangular, narrowly contiguous with sternite 3

Abdomen Somite 2 with 8 10 large spines, evenly spaced along anterior ridge, with stria behind anterior ridge Somites 3 4 with 2 striae behind anterior ridge Somite 6 posteromedian margin slightly concave Telson with numerous transverse squamae, greatest width 1 6 × midlength, anterolateral margin concave

Eye Maximum corneal diameter 0 35 × distance between anterolateral spines

Antennule Basal article (distal spines excluded) not overreaching corneae, distolateral and distomesial spines subequal, 2 lateral spines, proximal smaller, longer lateral spine reaching end of distal spines

Antenna Article 1 with distomesial spine reaching distal margin of article 2 Article 2 distomesial spine nearly reaching distal margin of article 4, distolateral spine reaching midlength of article 3 Articles 3 and 4 unarmed

Maxilliped 3. Ischium 1 8 × length of merus, with small flexor distal spine Merus flexor margin with large spine and small distal spine, extensor margin without distal spine

P1 2 0 2 5 pcl, with plumose setae on inner margins, and some iridescent setae, merus 0 8 0 9 pcl, with row of 6 spines on dorsal margin, distomesial spine reaching midlength of carpus Carpus 0 4 × length of merus, length 0 9 1 1 × width, with 5 spines along the mesial margin Propodus 1 0 1 4 × merus length, fingers longer than palm, 0 5 0 6 × total propodus length, pollex with subdistal spine, outer margin unarmed, dactylus outer margin unarmed

P2 4 Long, slender, with few small scales on lateral surfaces of meri, carpi and propodi, extensor margin with plumose setae and few iridescent setae P2 and P3 similar in length, P4 shorter (P3 merus 0 9 1 0 × length of P2 merus, P4 merus 0 8 × length of P3 merus) P2 1 9 2 1 × pcl, merus 0 6 0 8 × pcl, length 6 × width, 3 4 × carpus length and 1 6 × propodus length, extensor margin with 9 spines including distal spine, flexor margin with 4 spines and well developed distal spine; carpus with 2 extensor spines a distal flexor spine, propodus length 5 5 6 5 × height, with 5 movable flexor spines, dactylus 0 8 0 9 × propodus length, gently curved, length 6 7 × width, extensor margin densely lined with stiff short setae on distal half, flexor margin with 8 small moveable spines, space between spines increasing distally, unarmed along distal 1 5 End of P2 carpus overreaching end of P1 merus P3 with similar spination and article proportions as P2, merus, propodus and dactylus as long as those of P2 P4 length 0 85 × P2 length, merus 0 5 0 6 × pcl, merocarpal articulation reaching hepatic marginal spine of carapace

Egg diameter 0 5 mm

Colour Carapace and abdominal somites 2 3 pink Rostrum and supraocular spines white P1 pale pink with white fingers, P2 4 pale pink on meri and carpi, white on propodi and dactyli

Genetic data. COI and 16S, see Table 1

Etymology. After the type locality near the Abrolhos Islands, used as a noun in apposition

Remarks. Munida abrolhos sp nov is similar to *M. andamanica* Alcock, 1894, *M. rosula* Macpherson, 1994, and *M. curvirostris* Henderson, 1885, with a dorsally curving spiniform rostrum, P1
Figue 1 *Munida abrolhos* sp. nov., holotype, ovigerous female cl 23 mm, pcl 14 mm (WAM C78556): A, carapace and abdomen, dorsal view, B, rostrum, lateral view, C, right chela, dorsal view, D, left antenna and antennule, ventral view; E, sternum; F, abdominal somite 6, telson and right uropod G, ovigerous female cl 22 9 mm, pcl 14 4 mm (NMV J55036), anterolateral margin of carapace Scale A C, F 5 mm, D, E, G 2 mm

fixed finger with only subterminal spine (without marginal spines on lateral margin), and abdominal somite 2 with a row of 6 8 spines and at most 4 transverse ridges. Most clearly the new species differs from these species as it usually has only 4 branchial spines, although sometimes a smaller third branchial spine is present. In addition, postcervical spines, present in *M. abrolhos* sp. nov., are always absent in the aforementioned species.

Of those species with 4 branchial spines, *M. abrolhos* sp nov. is most similar to *M. keiensis* Baba, 2005, in having subequal distal spines of the basal antennular article, and the distomesial spine of antennal article 2 overreaching article 3 but not distinctly overreaching article 4. The two species can be distinguished by the shape of the anterior margin of thoracic sternite 4, which is broadly rounded in *M. keiensis* but subtriangular in *M. sp nov.*

Sequence divergence between *M. abrolhos* sp nov. and *M. rosula* is 3% for COI and 0 8% for 16S.

Distribution. Presently known only from off Western Australia, 658 754 m.

Munida galalala sp. nov.

http zoobank org urn lsid zoobank org:act.83168BC4 60EA 4710 A32B 42AAFFF985CA

Figures 4, 5

Type material Holotype WAM C78558, male (cl 17 8 mm, pcl 11 5 mm), Western Australia, Leveque L27 transect, 14° 33 432' S, 121° 20 388' E to 14° 2 772' S, 121° 19 644' E, 924–1101 m, SS05 2007 156, 3 July 2007 to 4 July 2007.

Description. Carapace Length 1 1 × greatest width, widest at midlength. Dorsal surface with main transverse ridges mostly uninterrupted and some short secondary transverse striae between main ridges on anterior half, ridges and striae lined with short, non iridescent setae. Gastric region slighly elevated, with 2 pairs of epigastric spines, longest pair behind supraocular spines. Hepatic region granular, parahepatic spine absent. Anterior part of branchial region between cervical groove and postcervical groove with few short scale like ridges and tubercles, postcervical spine absent, posterior part of branchial region with 5 main transverse ridges (excluding posterodorsal ridge) and few short secondary striae laterally between main ridges. Cardiac region with 4 main transverse ridges. Intestinal region with short median stria, posterodorsal ridge distinct, slightly convex medially, without secondary stria. Frontal margin inclined posteriorly at 110° from midline. Lateral margins slightly convex, anterolateral spines parallel, horizontal, reaching sinus between rostrum and supraocular spine; marginal hepatic spine anterior to cervical groove also strong, although distinctly shorter than anterolateral spine, branchial margin with 5 spines. Rostrum spiniform, gentle curving upwards, length 0 7 pcl, supraocular spine 0 45 × length of rostrum. Epistomial ridge curved ending anterior to antennal gland, mesial protuberance distinct.

Thoracic sternum. Surface smooth, without striae. Sternite 3 0 4 width of sternite 4, median length of sternal plastron (sternites 4 -7) 0 6 width of sternite 7. Sternite 4 anterior margin subtrapezoid, broadly contiguous with sternite 3.

Abdomen. Somite 2 with 7 prominent spines along anterior transverse ridge. Somites 2 4 each with 1 uninterrupted stria behind anterior ridge, without striae at lateral margins. Somite 6 posteromedian margin almost straight. Telson with numerous transverse squamae, greatest width 1 5 × median length, anterolateral margin concave.

Eye. Maximum corneal diameter 0 15 × distance between anterolateral spines.

Antennule. Basal article (distal spines excluded) overreaching corneae, well developed distolateral spine much longer than short distomesial spine, 2 lateral spines, proximal smaller, not exceeding distal spines.

Antenna. Article 1 with strong distomesial spine not reaching distal margin of article 2. Article 2 distomesial spine not overreaching distal margin of article 3, distolateral spine reaching distal margin of article 3. Article 3 distomesial spine almost reaching distal margin of article 4. Article 4 unarmed.

Maxilliped 3. Ischium 1 3 × merus length, with small flexor distal spine. Merus with 2 large spines on flexor margin and 1 small spine, extensor margin unarmed.

P1 3 0 × pcl, covered in plumose setae, without iridescent setae, merus 1 2 × pcl, with row of 6 dorsal spines and 2 rows of spines on mesial margin, distal spines strong, distomesial spine not reaching midlength of carpus. Carpus 0 6 × merus length, length 2 6 × width, with spines along mesial and dorsal margins. Propodus 1 2 × merus length, fingers slightly shorter than palm, 0 5 × total propodus length, pollex with small subdistal spine, margin unarmed, dactylus outer margin unarmed.

P2 4 Moderately long, slender, with numerous scales on lateral surfaces of meri, extensor margin with row of plumose setae. P2 length 2 1 × pcl, merus as long as pcl, length 7× height, 3 5 × carpus length and 1 4 × propodus length, with well developed spines on extensor margin, increasing in size distally, flexor margin with row of small spines and well developed distal spine; carpus with large spine and distal spine on extensor margin, distal spine on flexor margin, propodus length 6 5 × height, with 5 small movable flexor spines, dactylus compressed, slightly curved, 0 6 × propodus length, length 5 5 × width, with 9 movable spines evenly spaced along flexor margin including spine at base of unguis. End of P2 carpus reaching end of P1 merus. P3 missing. P4 length 0 8 × P2 length, merus 0 7 × pcl, merocarpal articulation almost reaching hepatic marginal spine of carapace.

Genetic data. COI and 16S, see Table 1

Etymology. Named *galalala*, meaning lobster in Dambimangari language, used as a noun in apposition.

Remarks. Munida galalala sp nov belongs to the group of species having five spines on the lateral branchial margins of the carapace, smooth thoracic sternites, small eyes, and spines on the anterior ridge of abdominal somite 2. The antennal peduncle is most similar to *Munida parvioculata* Baba, 1982, both species having a distinct distomesial spine on antennal peduncle article 3. The new species differs in

the generally smooth surface of the carapace with widely spaced transverse striae, compared to rugose with interrupted transverse ridges in *M. parvioculata*
Figure 4 *Munida galalala* sp nov , holotype, male 17 8 mm (WA M C 78558) A, carapace and abdomen, dorsal view; B, right chela, dorsal view, C, left antenna and antennule, ventral view; D, abdominal somite 6, telson and right uropod E, sternum Scale A E · 2 mm

Description. Carapace Length 0 9 × greatest width, widest at midlength Dorsal surface with main transverse ridges mostly uninterrupted, with secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae Gastric region with 3 6 pairs of epigastric spines, longest pair behind supraocular spines Hepatic region with short striae, small parahepatic spine sometimes present Anterior part of branchial region between cervical groove and postcervical groove with about 6 ridges and some shorter striae, posterior part of branchial region with about 12 transverse ridges (excluding posterodorsal ridge) Cardiac region with 3 or 4 main transverse ridges Intestinal region with 2 or 3 striae, posterodorsal ridge distinct, with secondary stria Frontal margin inclined posteriorly at 105° from midline Lateral margin slightly convex, anterolateral spines parallel, horizontal, just reaching sinus between rostrum and supraocular spine, marginal hepatic spine anterior to cervical groove, much shorter than anterolateral spine, branchial margins with 5 spines Rostrum laterally compressed, dorsal margin straight, inclined dorsally, ventral margin strongly convex, deepest slightly anterior to midlength, length 0 4–0 5 × pcl, supraocular spine 0 4 × length of rostrum Epistomial ridge straight, ending at antennal gland, mesial protuberance distinct

Thoracic sternum Median length of sternal plastron (sternites 4 7) 0 5 × width of sternite 7 Sternites 4 5 with striae; sternite 6 with few striae Sternite 3 0 4 width of sternite 4 Sternite 4 anterior margin subtrapezoid, narrowly contiguous with sternite 3

Abdomen Somite 2 with 8 small spines evenly spaced along anterior ridge Somites 2 4 with about 5, 7 and 12 uninterrupted striae behind anterior ridge, respectively, and squamae at lateral margins Somite 6 posteromedian margin almost straight Telson with numerous transverse squamae; greatest width 1 7 × median length, anterolateral margin concave

Eye Maximum corneal diameter 0 3 × distance between anterolateral spines

Antennule Basal article (distal spines excluded) not overreaching corneae; distolateral and distomesial spines subequal, 2 lateral spines, proximal smaller, longer lateral spine exceeding distal spines

Antenna Article 1 with distomesial spine reaching midlength of article 2 Article 2 with distomesial spine reaching distal margin of article 4, distolateral spine almost reaching distal margin of article 3 Article 3 and 4 unarmed

Maxilliped 3 Ischium 1 8 × merus length, with flexor distal spine Merus with large spine and small distal spine on flexor margin, extensor margin unarmed

P1. 1 6 1 9 pcl (females), 1 7 2 1 pcl (males), covered in plumose setae and iridescent setae in inner margin, merus 0 6 0 7 pcl (females), 0 7 0 8 pcl (males), with row of 5 small spines on dorsal margin, distomesial spine reaching midlength of carpus Carpus 0 4 (females), 0 4 0 5 (males) × merus length, length 0 9 1 1 × width, with 5 spines along the mesial margin Propodus 1 2 1 3 (females), 1 1 1 6 (males) × merus length, dactylus longer than palm, 0 5 × total propodus length, dactylus and pollex outer margin unarmed

P2 4 Relatively stout, with scales on lateral surface of meri, carpi and propodi, extensor margin with plumose setae and iridescent setae Meri shorter posteriorly (P3 merus 0 9 × P2 merus length, P4 merus 0 8 × P3 merus length) P2 1 8 2 2 × pcl, merus 0 6 0 8 × pcl, length 4 × width, 2 6 3 0 × carpus length and 1 3 1 6 × propodus length, extensor margin with 11 17 spines, flexor margin with acute ridges and well developed distal spine, carpus with 2 large spines and 2 or 3 smaller spines on extensor margin, distal spine on flexor margin, propodus length 5 × height, with 6 8 movable flexor spines, dactylus 0 7 0 9 × propodus length, curved, length 5 6 × width, extensor margin densely lined with stiff long setae on distal half, flexor margin with 8 12 spines, space between spines increasing distally, unarmed along distal 1 5 End of P2 carpus almost reaching end of P1 merus P3 with similar spination and article proportions as P2, merus slightly shorter than P2 merus (0 9), propodus and dactylus as long as those of P2 P4 length 0 8 × P2 length, merus 0 5 × pcl, merocarpal articulation reaching hepatic marginal spine of carapace

Egg diameter 0 5 mm

Colour. Carapace and abdominal somites 2 3 orange, remaining abdomen and telson white Rostrum white with red subdistal spot, supraocular spines orange Chelipeds and walking legs with transverse white pale orange and dark orange bands, distal half of palm and proximal half of cheliped fingers orange, distal half of fingers of cheliped white, dactyli of walking legs white

Genetic data. COI and 16S, see Table 1

Etymology. Named *julumunyju* with approval of the Kariyarra people The word julumunyju means prawn in Kariyarra language; used as a noun in apposition

Remarks. Munida julumunyju sp nov is very similar to *M. rubridigitalis* Baba, 1994, described from Queensland, Australia Both species have a laterally compressed rostrum with a red mark and red cheliped fingers, the second abdominal somite with 8 or 9 spines along the anterior ridge and subequal distal spines on the basal antennular article Comparison of *M. julumunyju* with paratypes of *M. rubridigitalis* and additional specimens from eastern Australia found that the two species differ chiefly in the shape of the rostrum The rostrum of both species is laterally compressed, but shallower and more evenly tapered in *M. rubridigitalis*. In *M. rubridigitalis*, the ventral rostral margin is gently convex with the dorsal and ventral margins parallel for the proximal half or slightly more, after which they gently converge to the apex In *M. julumunyju* sp nov, however, the rostrum is deeper, with the dorsal and ventral margins distally diverging, reaching the greatest depth slightly anterior to the midlength and then converging to the apex, making the ventral margin more strongly convex than in *M. rubridigitalis* In addition, *M. rubridigitalis* usually has a spine on the mesial margin of the antennal article 2 (occasionally present only on one side), which is always absent in *M. julumunyju* Colour in life may also be helpful in distinguishing these species The new species has a red patch on the pterygostomian flap below the linea anomurica, which is noted as absent in *M. rubridigitalis* by Baba (1994) In *M. julumunyju* sp nov the fingers are completely red with a

white tip, whereas *M. rubridigitalis* is described with only the distal half of the fingers red

We examined six specimens identified as *M. rubridigitalis* from New Caledonia in the collections of the MNHN, and herein we identify these specimens as *M. julumunyju* sp. nov. These specimens agree with *M. julumunyju* sp. nov. in rostral form and lack of a spine on the mesial margin of antennal article 2. Specimens reported and figured from New Caledonia and the Loyalty Islands as *Munida* sp. by Macpherson (1994 fig. 13b, 90) also agree with *M. julumunyju* in rostral form and the colour of the fingers, which are described as red with a white tip. Sequence divergence between *M. julumunyju* sp. nov. and a New Caledonian specimen of *"M. rubridigitalis"* (MNHN IU 2014 15474) is 4% (COI) and 0.6% (16S). Thus, further study is required to determine if other reported specimens of *"M. rubridigitalis"* from the New Caledonian region are conspecific with, or distinct from, *M. julumunyju* sp. nov. The apparently disjunct distribution of *M. julumunyju* sp. nov. suggests that it can be expected to occur at intermediate localities, possibly off southern Indonesia and Papua New Guinea.

Distribution. Presently known from off Western Australia, 373 450 m. New Caledonia, 450 515 m. Loyalty Islands, 540 m.

Figures 8, 9

Type material. Holotype WAM C78561, ovigerous female (cl 14.7 mm, pcl 9 mm), Western Australia, off Imperieuse Reef, 17° 35.982' S, 118° 59 076' E to 17° 38 574' S, 119° 01 26' E, 222 319 m, SS05 2007 63, 16 June 2007.

Description. Carapace. Length 1.1 ∧ greatest width, widest at midlength. Dorsal surface with numerous uninterrupted transverse ridges and secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae. Gastric region with 5 pairs of epigastric spines, longest pair behind supraocular spines. Parahepatic, postcervical and dorsal branchial spine present. Anterior part of branchial region between cervical groove and postcervical groove with 3 main ridges, posterior part of branchial region with 6 main transverse ridges (excluding posterodorsal ridge) and 5 secondary striae laterally between main ridges. Cardiac region with 5 main transverse ridges. Intestinal region with transverse ridge, posterodorsal ridge and secondary stria. Frontal margin inclined posteriorly at 112° from midline. Lateral margins slightly convex, anterolateral spines parallel, horizontal, overreaching sinus between rostrum and supraocular spine, small hepatic marginal spine in front of cervical groove (0.15 ∧ length of anterolateral spine), branchial margin with 4 spines. Rostrum spiniform, horizontal, 0.7 ∧ pcl, supraocular spine 0.5 ∧ length of rostrum. Epistomial ridge straight ending slightly anterior to antennal gland, mesial protuberance distinct.

Thoracic sternum. Sternal surface smooth, sternite 4 with few short striae. Sternite 3 0.4 width of sternite 4, midlength of sternal plastron (sternites 4 7) 0.5 width of sternite 7. Sternite 4 anterior margin broadly rounded.

Abdomen. Somite 2 with 2 pairs of small spines at lateral margins of anterior transverse ridge. Somites 2 4 each with 2 or 3 uninterrupted striae behind anterior ridge and some shorter striae. Somite 6 posteromedian margin almost straight. Telson with numerous transverse squamae, greatest width 2.0 ∧ median length, anterolateral margin almost straight or shallowly concave.

Eye. Maximum corneal diameter 0.36 ∧ distance between anterolateral spines.

Antennule. Basal article (distal spines excluded) overreaching or reaching end of corneae; 2 well developed distal spines, distomesial slightly longer than distolateral, 2 lateral spines, proximal small, distolateral spine exceeding both distal spines.

Antenna. Article 1 with strong distomesial spine overreaching distal margin of article 4. Article 2 with strong distomesial spine overreaching distal margin of article 4, distolateral spine reaching distal margin of article 4, 2 small lateral spines on mesial margin. Articles 3 and 4 unarmed.

Maxilliped 3. Ischium 1.45 × merus length, with strong flexor distal spine; merus with strong spine on flexor margin and small spine distally, with small spine on distal extensor margin.

P1 length 3.0 ∧ pcl, with iridescent setae on inner margin. Merus 1.25 ∧ pcl, with a row of 5 dorsal spines and row of 5 long, close set spines on mesial margin, distal spines strong, distomesial spine not reaching midlength of carpus. Carpus 0.4 ∧ merus length, length 2.6 ∧ width, with spines along mesial and dorsal margins. Propodus 1.1 × merus length, fingers 0.5 ∧ total propodus length, with 2 small distolateral spines, dactylus with small proximal spine small subdistal spine.

P2 4. Long and slender, with numerous scales on lateral surfaces of meri, margins with row of plumose setae and iridescent setae on ischium and merus. P2 length 2.6 ∧ pcl, merus as long as pcl, length 6 ∧ height, 4.0 ∧ carpus length and 1.2 ∧ propodus length, extensor margin spinose, flexor margin with small spine near distal one fifth and well developed distal spine, carpus extensor margin with 3 small spines (broken on right P2 of the holotype) and prominent distal spine, flexor margin with distal spine, propodus length 9.3 ∧ height, with 11 small movable flexor spines, dactylus compressed, slightly curved, length 0.5 ∧ propodus length and 5 ∧ height, with 10 evenly spaced spines along distal 0.8 of flexor margin. End of P2 carpus reaching end of P1 merus. P3 with similar spination and article proportions as P2, merus slightly shorter than P2 merus (0.85), propodus and dactylus as long as those of P2. P4 length 0.9 ∧ P2 length, merus 0.7 ∧ pcl, 0.8 ∧ P3 merus length, propodus 0.85 and dactylus 0.95 ∧ length of those of P3, merocarpal articulation slightly overreaching anterolateral corner of carapace.

Genetic data. COI and 16S, see Table 1

Etymology. Named *jurunjurun* with the approval of Bardi elders, after Jurun jurun, meaning crayfish in Bardi, used as a noun in apposition.

Remarks. *Munida jurunjurun* sp. nov. is closest to *M. acantha* Macpherson, 1994, from New Caledonia, both species having antennal articles 1 and 2 with long mesial spines overreaching article 4, antennule with distomesial spine longer than
Figure 8 *Munida jurunjurun* sp. nov , holotype, ovigerous female cl 14 7 mm, pcl 9 mm (WAM C78561) A, carapace and abdomen, dorsal view, B, right chela, dorsal view, C, right antenna and antennule, ventral view; D, sternum; E, abdominal somite 6, telson and right uropod Scale: A E 2 mm

distolateral spine, a smooth thoracic sternum, and abdominal somite 2 with small spines limited to the lateral margins of the anterior ridge. The new species differs from *M. acantha* in having 4 rather than 5 branchial carapace spines. In addition, the new species has a distinct row of spines on the mesial margin of the P1 merus, which are close set on the distal half of the article, rather than more evenly spaced along the distal 0.6 as in *M. acantha*. Sequence divergence between *M. acantha* and *M. jurunjurun* sp. nov. is 8% for COI and 3.5% for 16S.

Of those species with 4 branchial spines, *M. jurunjurun* sp. nov. is similar to *M. albiapicula* Baba and Yu, 1987, *M. zebra* Macpherson, 1994, *M. volantis* Macpherson, 2004, and *M. nesiotes* Macpherson, 1999, all of which have a long mesial spine on antennal articles 1 and 2. In these species, however, the spines on the anterior ridge of abdominal somite 2 are evenly spread along the entire margin, rather than placed at the lateral extremities.

Distribution. North western Australia, off Imperieuse Reef, 222–319 m.
Figure 9. *Munida jurunjurun* sp. nov., holotype, ovigerous female cl 14.7 mm, pcl 9 mm (WAM C78561): A, right P2 dactylus, lateral view; B, right P2, lateral view; C, right P3, lateral view; D, right P4, lateral view; E, left maxilliped 3, lateral view. Scale A – 1 mm, B–E – 2 mm

Paratypes (all Western Australia) WAM C78563, 1 ovigerous female (cl 7 2 mm, pcl 5 mm), 7 females (cl 6 0 mm, pcl 3 8 mm to cl 8 5 mm, pcl 5 5 mm), 7 males (cl 6 3 mm, pcl 3 8 mm to cl 9 1 mm, pcl 6 2 mm), collected with holotype, NMV J55046, 1 male (cl 8 7 mm, pcl 5 9 mm), 1 ovigerous female (cl 7 9 mm, pcl 5 2 mm), collected with holotype, NMV J55100, 2 ovigerous females (cl 7 7 mm, pcl 5 0 mm, cl 7 8 mm, pcl 5 1 mm), 1 female (cl 7 8 mm, 5 0 mm), collected with holotype, NMV J56100, 1 juvenile (cl 4 4 mm, pcl 3 0 mm), 1 ovigerous female (broken rostrum, pcl 4 8 mm), Imperieuse L23 transect, 18° 27 612' S, 120° 08 682' F to 18° 2772' S, 120° 08 682' F, 80 81 m, SS05 2007 82, 16 June 2007

Description. Carapace Length 1 1 ∧ greatest width, widest at midlength Dorsal surface with main transverse ridges mostly uninterrupted, without secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae and few long iridescent setae. Gastric region with 5 or 6 pairs of epigastric spines, longest pair behind supraocular spines, with median row of 2 or 3 small spines behind rostrum Hepatic region with 3 or 4 spines on dorsal surface, parahepatic spines present Anterior part of branchial region between cervical groove and postcervical groove with 3 ridges and 1 or 2 small spines, 1 postcervical spine, posterior part of branchial region with 4 or 5 main transverse ridges (excluding posterodorsal ridge) and few shorter secondary striae between main ridges Cardiac region with 3 main transverse ridges Intestinal region without striae, posterodorsal ridge distinct, without secondary stria Frontal margin inclined posteriorly at 115° from midline. Lateral margin slightly convex, anterolateral spines parallel, horizontal, not reaching sinus between rostrum and supraocular spine, hepatic marginal spine shorter than anterolateral spine; branchial margin with 5 spines Rostrum spiniform, slightly sinuous in profile, length 0 5 ∧ pcl, supraocular spine 0 3 ∧ length of rostrum Epistomial ridge curved, ending anterior to antennal gland, mesial protuberance distinct

Thoracic sternum Sternital surface smooth, sternite 4 with few long striae Sternite 3 0 4 width of sternite 4, midlength of sternal plastron (sternites 4 7) 0 7 width of sternite 7 Sternite 4 anterior margin truncate, entirely contiguous with sternite 3

Abdomen Somite 2 without spines Somites 2 4 each with 2 or 3 uninterrupted striae behind anterior ridge and striae at lateral margins Somite 6 posteromedian margin almost straight Telson with numerous transverse squamae; greatest width 2 0 ∧ median length, anterolateral margin concave

Eye Maximum corneal diameter 0 35 ∧ distance between anterolateral spines

Antennule Basal article (distal spines excluded) not overreaching corneae; distolateral and distomesial spines subequal, 2 lateral spines, proximal smaller, longer lateral spine exceeding distal spines

Antenna Article 1 with distomesial spine reaching midlength of article 2 Article 2 distomesial spine slightly overreaching distal margin of article 3, distolateral spine almost reaching distal margin of article 3 Article 3 unarmed or with small distolateral spine. Article 4 unarmed

Maxilliped 3 Ischium 1 6 ∧ merus length, with distal flexor spine Merus with 3 well developed spines on flexor margin, extensor margin with small distal spine

P1 length 3 1 4 4 pcl (males), 2 8 3 0 pcl (females), with dense covering of iridescent setae on inner margins of merus (without plumose setae), merus 1 3 1 4 (males), 1 0 1 1 (females) ∧ pcl, with row of 5 subtriangular spines on dorsal and mesial margin, distomesial spine not reaching midlength of carpus Carpus 0 3 0 4 ∧ merus length, length 1 9 (males), 2 0 2 4 (females) ∧ width, with spines along mesial margin Propodus 1 6 1 7 (males), 1 4 (females) ∧ merus length, fingers 0 4 0 6 (males), 0 5 0 6 (females) ∧ total propodus length, pollex with row of small spines along outer margin, dactylus with 3 small spines on outer margin

P2 4 Moderately long and slender, with scales on lateral surfaces of meri, extensor margin with plumose setae and iridescent setae P2 length 2 1 2 6 ∧ pcl, merus as long as carapace, length 6 4 × height, 3 4 ∧ carpus length and 1 3 ∧ propodus length, extensor margin spinose, flexor margin with acute ridges, 1 or 2 spines and well developed distal spine, carpus with 4 small extensor spines, distal spine on extensor and flexor margin, propodus length 7 ∧ height, with 10 14 movable flexor spines, dactylus compressed, almost straight, 0 7 0 9 ∧ propodus length, length 6 7 ∧ height, flexor margin with 7 12 spines, unarmed along distal 1 3 End of P2 carpus not reaching end of P1 merus P3 with similar spination and article proportions as P2, merus slightly shorter than P2 merus (0 8), propodus and dactylus as long as those of P2 P4 length 0 8 ∧ P2 length, merus 0 6 0 7 ∧ pcl, 0 9 ∧ P3 merus length, merocarpal articulation almost reaching marginal hepatic spine of carapace

Genetic data. COI and 16S, see Table 1

Etymology Named after the Leeuwin current which flows off the west coast of Australia, used as a noun in apposition

Remarks. *Munida leeuwin* sp nov is most similar to *M. roshanei* Tirmizi, 1966, *M. janetae* Tirmizi and Javed, 1992, and *M. arabica* Tirmizi and Javed, 1992, described from the western Indian Ocean These three species are very similar to each other and have been distinguished by the length of the pereopod 1 chela, the ratio of the length of the fingers to the propodus palm, and the shape of sternite 3 In his key, Baba (2005) characterises *M. janetae* as having cheliped fingers that are distinctly longer than the palm, while the fingers are shorter than the palm in *M. roshanei* and *M. arabica*. In *M. leeuwin* sp nov , the fingers are usually as long as the palm but are occasionally longer or shorter than the palm (0 4 0 6 ∧ propodus length) We tentatively describe this species as new based on a combination of subtle differences from the aforementioned species and significant molecular divergence from material we identify as *M. roshanei* In *M. leeuwin* sp nov , the dactyli of P2 4 are slender and
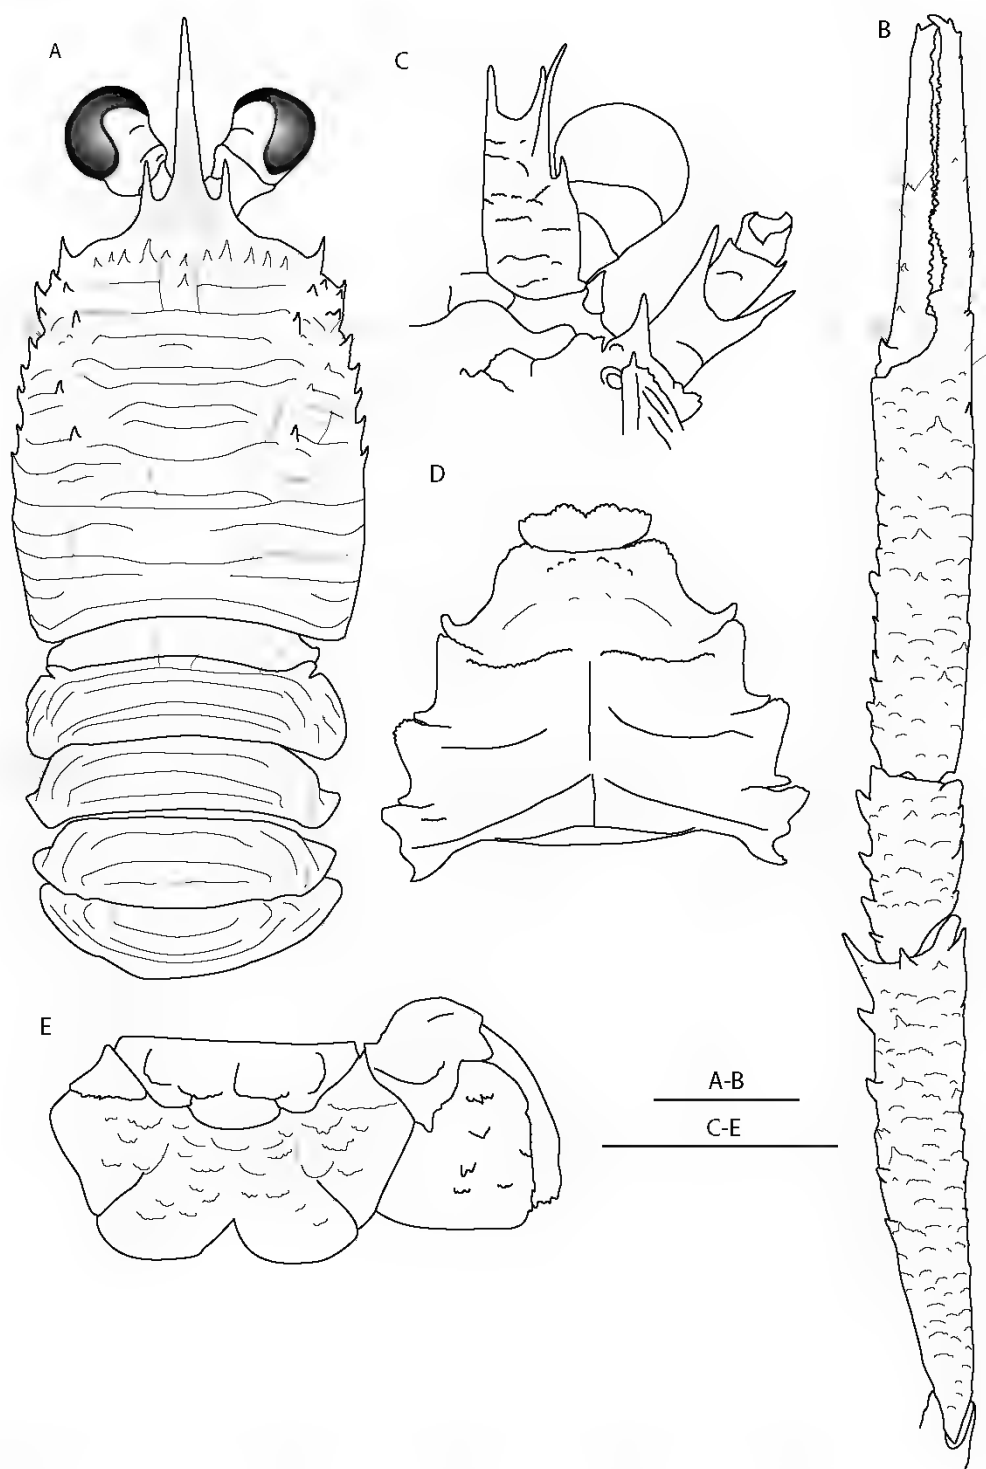

Figure 10 *Munida leeuwin* sp nov, holotype, male cl 8.1 mm, pcl 5 3 mm (WAM C78562) A, carapace and abdomen, dorsal view; B, right chela, dorsal view, C, left antenna and antennule, ventral view, D, sternum; E, abdominal somite 6, telson and right uropod Scale: A E · 2 mm

unarmed on the distal one third of the flexor margin, with the ultimate spine closer to the penultimate spine than the unguis This differs from *M. janetae* in which the dactyli have spines regularly arranged along the entire flexor margin (Tirmizi and Javed, 1992) Illustrations of *M. arabica* show the dactyli to be similar to those of *M. leeuwin* sp nov., but *M. arabica* can be distinguished by the presence of distal spines on antennal article 4, which are always absent in *M. leeuwin* sp. nov. The type description of *M. roshanei* lacks a description or illustration of the dactyli, as does that of Lewinsohm (1969) for nearby Red Sea specimens Specimens identified as *M. roshanei* from the Phillipines (Baba, 1988) and Australia (present study), however,

have the dactyli with spines regularly arranged along the entire flexor margin. Although the spination of the P2 4 dactyli of the type material of *M. roshanei* remains to be confirmed, given the brevity of the original description and without access to the type, we fully describe *M. leeuwin* as new to improve the taxonomy of this difficult group

The genetic sequences of *M. leeuwin* are highly divergent from all other species analysed Despite their morphological similarities, *M. leeuwin* and our specimens of *M. roshanei* are divergent by 12% in COI

Distribution. Presently known only from off Western Australia, 658 754 m
Figure 11 *Munida leeuwin* sp. nov., holotype, male cl 8.1 mm, pcl 5 3 mm (WAM C78562): A, right P2 dactylus, lateral view, B, right P2, lateral view, C, right P3, lateral view; D, right P4, lateral view; E, left maxilliped 3, lateral view Scale A E 1 mm

Description. Carapace As long as greatest width, widest at midlength Dorsal surface with main transverse ridges mostly uninterrupted, without secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae Gastric region with 3 pairs of epigastric spines and 1 or 2 small additional spines, without median row of spines behind rostrum Hepatic region without spines on dorsal surface Anterior part of branchial region between cervical groove and postcervical groove with 2 or 3 short tuberculate ridges and often 1 small spine anteriorly, posterior part of branchial region with 5 transverse ridges (excluding posterodorsal ridge) Cardiac region with 2 main transverse ridges Intestinal region without striae, posterodorsal ridge distinct, without secondary stria Frontal margin strongly oblique, inclined posteriorly at 115° from midline Lateral margin slightly convex, anterolateral spine very small, far from reaching sinus between rostrum and supraocular spine, hepatic marginal spine slightly smaller than anterolateral spine, branchial margin with 5 spines Rostrum spiniform, 0 5 × pcl, supraocular spine 0 25 × length of rostrum, exceeding eyes Epistomial ridge straight ending at antennal gland, mesial protuberance distinct

Thoracic sternum Sternal suface smooth, sternite 4 with only few striae Sternite 3 0 4 × width of sternite 4 Sternite 4 anterior margin triangular, narrowly contiguous with sternite 3 Midlength of sternal plastron (sternites 4 7) 0 5 × width of sternite 7

Abdomen. Somites smooth without spines, distinct ridges or striae Somite 6 posteromedian margin slightly concave Telson with few striae, greatest width 1 2 × median length, anterolateral margin weakly concave

Eye Maximum corneal diameter 0 18 × distance between anterolateral spines

Antennule Basal article (distal spines excluded) overreaching corneae, distolateral spine much longer than distomesial spine, 2 lateral spines, proximal smaller, longer lateral spine not reaching end of distolateral spines

Antenna Article 1 distomesial spine almost reaching distal margin of article 2 Article 2 distomesial spine reaching distal margin of article 3, distolateral spine not reaching midlength of article 3 Articles 3 and 4 unarmed

Maxilliped 3 Ischium 1 9 × merus length, without flexor distal spine. Merus with large median spine and distal spine on flexor margin, extensor margin without distal spine

P1 Length 2 4 3 2 × pcl, covered in rows of short plumose setae Merus length 0 9 1 1 × pcl, with row of 2 large spines and 2 small spines on dorsal margin, 1 strong spine on dorsolateral margin, and 4 spines on mesial margin, distomesial spine not reaching midlength of carpus Carpus 0 5 × merus length, length 3 0 × width, with 6 spines along mesial margin Propodus 1 3 × merus length, palm with row of 3 or 4 spines on dorsal surface of palm, fingers 0 4 0 5 × total propodus length, without spines on outer margins

P2 4 Long and slender, with few small scales on lateral sides of meri and carpi, extensor margin with short plumose setae and few longer setae P2 1 8 2 3 × pcl, merus 0 7 0 8 × pcl, length 8 0 × width, 3 0 × carpus length and 1 5 × propodus length, extensor margin with 5–7 spines, flexor margin with 3 spines and well developed distal spine, carpus extensor margin with spine at midlength and distal end, flexor margin with distal spine, propodus length about 8 × height, with 5 movable flexor spines on flexor margin, dactylus gently curved distally, 0 6 0 7 × propodus length, length about 7 × height, extensor margin densely lined with stiff short setae on distal half, flexor margin armed along entire length with 12 14 movable spines including spine at base of unguis End of P2 carpus not reaching end of P1 merus P3 with similar spination and article proportions as P2, merus 0 9 × P2 merus length, propodus and dactylus as long as those of P2 P4 length 0 7 0 8 × P2 length, merus length 0 3 0 5 × pcl, propodus and dactylus similar in length to those of P3, merocarpal articulation reaching hepatic marginal spine carapace

Egg diameter 0 65 mm

Colour in life. Carapace pink anteriorly fading to white at posterior, abdominal somite 2 white, somites 3 6 pink P1 and P2 4 white

Genetic data. COI and 16S, see Table 1

Etymology. Named *lutruwita*, the original name of Tasmania in *palawa kani*, the language of the Tasmanian Aboriginal people, with the approval of the Tasmanian Aboriginal Centre, used as a noun in apposition

Remarks Munida lutruwita sp nov is very close to *M. manqingae* Liu, Lin and Huang, 2013, described from a single female specimen collected from hydrothermal vent fields at 2218 m in the south western Indian Ocean The spination of the antenna and antennule is identical between the two species, but the new species differs from *M. manqingae* in the following

· the anterior branchial surface of *M. lutruwita* is rugose, with 2 or 3 rows of small tubercles and a small spine anteriorly, but smooth in *M. manqingae*

· the P2 dactylus has 12 14 movable flexor spines in *M. lutruwita*, but only 10 in *M. manqingae*.
Figure 12 *Munida lutruwita* sp nov , holotype, ovigerous female, cl 11 7 mm, pcl 7 8 mm (NMV J67481) A, carapace and abdomen, dorsal view, B, right chela, dorsal view, C, right antenna and antennule, ventral view, D, sternum, E, telson Scale A B   1 mm, C–E   2 mm

Munida lutruwita is also very similar to *Munida magniantennulata* Baba and Turkay, 1992, described from hydrothermal vents in the Lau Basin near Fiji, and the recently described, *M. alba* Liu, Li and Lin, 2020, from the Eastern Pacific Rise. Differences between the three species are as follows

- the antennal article 1 mesial spine reaches the end of article 2 in *M. lutruwita* and *M. alba*, but does not reach as far as the midpoint of article 2 in *M. magniantennulata*.

- the supraocular spines are parallel or slightly convergent, overreaching the eyes in *M. lutruwita*, while in *M. magniantennulata* and *M. alba*, the suproacular spines are slightly divergent and do not overreach the eyes

- the frontal margins of the carapace are oblique in *M. lutruwita* and *M. alba* rather than near transverse in *M. magniantennulata*.

- *M. lutruwita* and *M. magniantennulata* further differ from *M. alba* in the presence of the distal flexor spine on the maxilliped 3 merus (absent in *M. alba*) and unarmed outer margin of the cheliped pollex (spinose in *M. alba*)

Distribution. Off southern Tasmania and the Great Australian Bight, 1599–2040 m
Figure 13. *Munida lutruwita* sp. nov., holotype ovigerous female, cl 11.7 mm, pcl 7.8 mm (NMV J67481): A, right P2 dactylus, lateral view; B, left P2, lateral view; C, left P3, lateral view; D, left P4, lateral view; E, left maxilliped 3, lateral view. Scale · 1 mm.

Figures 14, 15

Munida aff *rubiesi* Macpherson, 1991 — Poore et al , 2008

Type material Holotype WAM C78564, male (rostrum broken, pcl 9 0 mm), Western Australia, south west of Kalbarri, 27° 56 106' S 113° 4 86' E to 27° 56.646' S 113° 5 28' F, 417 428 m, beam trawl, SS10 2005 98, 4 December 2005

Description. Carapace Length 1 2 ∧ greatest width, widest at midlength Dorsal surface with numerous uninterrupted transverse ridges and secondary transverse striae between main ridges, ridges and striae lined with short, non iridescent setae and scattered long setae Gastric region with 4 pairs of epigastric spines, longest pair behind supraocular spines Hepatic region with short scales, parahepatic spine present Anterior part of branchial region between cervical groove and postcervical groove with dorsal spine and 5 or 6 main ridges, 1 postcervical spine; posterior part of branchial region with 8 main transverse ridges (excluding posterodorsal ridge) and 5 secondary striae laterally between main ridges Cardiac region with 5 main transverse ridges Intestinal region with 2 transverse ridges, posterodorsal ridge distinct, with secondary stria Frontal margin inclined posteriorly at 106° from midline Lateral margins slightly convex, anterolateral spine slightly divergent, horizontal, overreaching sinus between rostrum and supraocular spine, hepatic marginal spine distinctly smaller than anterolateral spine, branchial margin with 5 spines Rostrum broken, supraocular spines 0 4 ∧ pcl, exceeding eyes Epistomial ridge straight ending slightly anterior to antennal gland, mesial protuberance distinct

Thoracic sternum Sternal surface smooth, sternites 4 and 5 with few short striae Sternite 3 0 4 ∧ width of sternite 4, median length of sternal plastron (sternites 4 7) 0 7 ∧ width of sternite 7 Sternite 4 anterior margin subtriangular, narrowly contiguous with sternite 3

Abdomen Somite 2 with 5 pairs of spines on anterior transverse ridge Somites 2 4 each with 5 or 6 uninterrupted striae behind anterior ridge Somite 6 posteromedian marginslightly convex, posterolateral margins slightly produced Telson with numerous transverse squamae, greatest width 1 6 ∧ median length, anterolateral margin slightly concave

Eye Maximum corneal diameter 0 4 ∧ distance between anterolateral spines

Antennule Basal article (distal spines excluded) overreaching corneae, 2 long, subequal distal spines, 2 lateral spines, proximal smaller, distolateral spine not exceeding distal spines

Antenna Article 1 with distomesial spine overreaching distal margin of article 2 Article 2 with strong distomesial spine significantly overreaching distal margin of article 4, distolateral spine reaching distal margin of article 3 Articles 3 and 4 unarmed

Maxilliped 3 Ischium 1 5 ∧ merus length, with strong flexor distal spine; merus with strong spine on flexor margin and small spine distally, without spine on distal extensor margin

P1 Length 2 8 ∧ pcl, with long plumose setae and

iridescent setae, setae longest on dorsal surfaces Merus length 1 1 ∧ pcl, with a row of 8 dorsal spines and row of 4 spines on mesial margin, distal spines strong, distomesial spine not reaching midlength of carpus Carpus 0 4 ∧ merus length, length 1 9 ∧ width Propodus 1 1 ∧ merus length, fingers 0 6 ∧ total propodus length, pollex with row of 5 spines on lateral margin, dactylus with row of 3 spines on dorsal margin, 5 spines on lateral margin and 1 small subdistal spine

P2 4 Long, slender, with numerous scales on lateral sides of meri, extensor margins with row of plumose and iridescent setae P2 length 2 3 ∧ pcl, merus as long as carapace, length about 7 ✕ height, 4 0 ∧ carpus length and 1 9 ∧ propodus length, row of spines on extensor margin, flexor margin row of spines and well developed distal spine, carpus with 2 small spines and 2 large spines on extensor margin, distal spine on flexor margin, propodus length 5 3 ✕ height, with 9 small movable flexor spines, dactylus compressed, almost straight, as long as propodus length, length 8 6 ∧ height, with 7 movable spines along the flexor margin, distal one quarter unarmed P3 with similar spination and article proportions as P2, merus slightly shorter than P2 merus (0 75), propodus and dactylus slightly shorter than those of P2 P4 length 0 6 ∧ P2 length, merus 0 4 ∧ pcl, length 0 6 ∧ P3 merus length, propodus 0 8 and dactylus 0 9 ✕ as long as those of P3

Etymology. Named *maatijada* for crawling and *kurnaaku* for crayfish yabbie in Nhanda language at the Nhanda Language Day (2 July 2019) at Bundiyarra Irra Wanga Language Centre in Geraldton, used as a noun in apposition

Remarks. Despite the broken rostrum in the holotype, *Munida maatijadakurnaaku* sp nov is clearly distinguished by a number of diagnostic characters It is most similar to *M. aequalis* Ahyong and Poore, 2004, from eastern Australia, which also has long and subequal distal spines on the basal antennular article, a subtriangular sternite 4, slender P2 4 dactyli and similar antennal spination The two species can be distinguished by

· the supraocular spines overreach the eyes in *M. maatijadakurnaaku* but do not reach the end of the eyes in *M. aequalis*

· antennal article 2 has the distomesial spine significantly overreaching article 4 in *M. maatijadakurnaaku*, but only slightly overreaching article 4 in *M. aequalis*

the P2 4 dactyli are as long as their respective propodi in the new species, with only the distal one quarter unarmed, rather than slightly shorter than the propodus and unarmed on the distal one third in *M. aequalis*

Distribution. Known only from Western Australia, 417–428 m

Munida agave **Macpherson and Baba, 1993**

Material examined. Western Australia NMV J56008, 1 female (cl 11 6 mm, pcl 10 4 mm), Broome L25 transect, 16° 45 156' S,
Figure 14. *Munida maatijadakurnaaku* sp. nov., holotype, 1 male with missing rostrum, pcl 9 0 mm (WAM C78564) A, carapace and abdomen, dorsal view; B, right chela, dorsal view; C, right antenna and antennule, ventral view; D, sternum; E, telson. Scale A E · 2 mm
Figure 15 *Munida maatjadakurnaaku* sp. nov., 1 male with missing rostrum, pcl 9.0 mm (WAM C78564): A, right P2 dactylus, lateral view; B, left P2, lateral view; C, left P3, lateral view; D, left P4, lateral view; E, left maxilliped 3, lateral view. Scale, A–E = 1 mm

121° 02.796' E to 16° 44.592' S, 121° 02.208' E, 100–108 m, SS05 2007 116, 30 June 2007, NMV J56099, Adele L28 transect, 14° 33.732' S, 122° 55.092' E to 14° 33.684' S, 122° 54.906' E, 95–105 m, SS05 2007 161, 4 July 2007.

Colour. Carapace and abdominal somites 2–5 pale orange with orange striae and spines; telson whiteish. Rostrum and supraocular spines orange. P1 and P2–4 pale orange with orange striae.

Genetic data. COI and 16S; see Table 1

Remarks. This specimen agrees well with the description of the holotype from the Philippines, having arcuate striae on sternites 3–6 and two pairs of spines on the anterior ridge of abdominal somite 2. This is the first record of the species from Australia.

Distribution. Japan, Philippines, Indonesia, Taiwan, 89–549 m. North-western Australia, 55–108 m

Material examined Western Australia NMV J55081, 1 male (cl 16 1 mm, pcl 10 2 mm),
Abrolhos, 28° 29 37' S, 113° 25 14' F to 28° 30 06' S, 113° 25 5' F, 416 431 m, SS10. 2005.95, 2005.

Colour. Carapace and abdominal somites pink white with orange reddish striae and spines Rostrum white with red tip, supraocular spines red at base and white distally, anterolateral spines red Walking legs with orange red bands Chela with orange bands

Genetic data. Not available

Remarks. This single specimen differs slightly from the type material of *M. armilla* Macpherson, 1994 In our specimen the basal article of the antennule has subequal distal spines while in the holotype the distomesial spine is slightly shorter than the distolateral In our specimen the carapace has interupted striae while the holotype has numerous scales This is the first record of the species from Australia

Distribution. New Caledonia, Matthew and Hunter Islands, Tuscaroa Bank, Tonga, French Polynesia (Tarava seamounts, Tuamoto and Society Archipelagos), 233 710 m Western Australia, 416 431 m

Munida asprosoma Ahyong and Poore, 2004

Figure 16C D

Munida asprosoma Ahyong and Poore, 2004: 20, fig 3 (type locality east of Broken Bay, New South Wales, Australia) — Baba et al , 2008 87 Baba et al , 2009 146, figs 123 126 Poore et al , 2011 pl 16D McEnnulty et al , 2011 app 1

Material examined Western Australia NMV J56016, 2 ovigerous females (cl 16 3 mm, pcl 10 2 mm, cl 17 4 mm, pcl 10 7 mm), Mermaid L24 transect, 16° 38 064' S, 119° 09 216' F to 16° 38 766' S, 119° 08 034' F, 983 993 m, SS05 2007 68, 17 June 2007,
NMV J56096, 1 female (cl 13 9 mm, pcl 8.3 mm), 1 juvenile (cl 10.3 mm, pcl 6 0 mm), Mermaid L24 transect, 16° 44 286' S, 119° 15 042' F to 16° 43 794' S, 119° 15 48' F, 693 698 m, SS05 2007 70, 17 June 2007, NMV J56393, 2 females (pcl 6 7 8 1 mm, #B, #A), 1 male (pcl 5 0 mm, #C), Leveque L27 transect, 14° 33 06' S, 121° 15 366' F to 14° 33 588' S, 121° 16 56' F, 1021 1023 m, SS05 2007 155, 3 June 2007, NMV J57258, 1 ovigerous female (cl 20 6 mm, pcl 12 7 mm), SS05 2007 155, NMV J55077, 1 male (cl 20 4 mm, pcl 12 2 mm), Perth Canyon, 31° 57 9' S, 115° 06.3' F to 31° 56 982' S, 115° 07 08' F, 928 1170 m, SS10 2005 73, 30 November 2005, NMV J55078, 4 ovigerous females (cl 18 7 mm, pcl 10 7 mm to cl 22 1 mm, pcl 13 6 mm), 19 females (cl 14 4 mm, pcl 8 6 mm to cl 23 5 mm, pcl 14 5 mm), 11 males (cl 12 4 mm, pcl 7 4 mm to cl 26 5 mm, pcl 15 9 mm), SS10 2005 73, NMV J55076, 3 males (cl 13 2 mm, pcl 8 0 mm to cl 21 5 mm, pcl 12 8 mm), Abrolhos, 29° 00 594' S, 113° 42 78' F to 29° 01 512' S, 113° 43 32' F, 700 704 m, SS10 2005 85, 2 December 2005, NMV J55079, 1 female (cl 16 9 mm, pcl 10 4 mm), 5 males (cl 15 9 mm, pcl 9 6 mm to cl 26 1 mm, pcl 16 1 mm), SS10 2005 85

Colour. Carapace, abdomen, chela and P2 4 pale pink Reddish on distal portion of fingers, antenna and posterior margin of carapace One specimen photographed is different in colour from the other two photographed specimens This specimen was collected from the Abrolhos station at ~700 m (male, cl 13 2 mm, pcl 8 0 mm, NMV J55076) The carapace is white with orange on the striae and abdominal somites 2 3, P2 4 are white, the chelae are orange with white fingers

Genetic data. COI, see Table 1

Remarks. The present specimens of *M. asprosoma* from Western Australia accord well in most respects with those from eastern Australia (Ahyong and Poore, 2004) Three juveniles (NMV J56393, pcl 5 0 8 1 mm), however, differ from adults in having lesser developed abdominal spination the median pair of spines on the anterior ridge of abdominal somite 2 is well developed but spines laterad are either incipent or minute, and the anterior ridge of somite 3 is unarmed Thus, the diagnostic spination of the abdominal somites may not be fully developed in juveniles and care should be taken when identifying small specimens

The COI sequences of *M. asprosoma* were only 1 3% divergent from *Munida hoda* Macpherson, Rodríguez Flores and Machordom, 2017, from Mozambique Intraspecific divergence between the three specimens sequenced here was 0 3 0 6% These species share a number of morphological characters including the presence of 5 spines on the branchial lateral margins of the carapace, strongly oblique frontal carapace margins, absence of secondary striae between the widely spaced primary striae, spines along the anterior ridge of the abdominal somite 2, large eyes, and the distomesial spine of the antennular article 1 shorter than the distolateral spine They can easily be distinguished by the presence of spines on abdominal somite 3 in adults of *M. asprosoma*, and the flexor spination of the P2 dactyli, with 7 9 spines in *M. asprosoma* and only 4 spines in *M. hoda* One of the specimens photographed had a different colour pattern from the others (NMV J55076, male pcl 8 0 mm, see above) but we could find no other morphological characters to distinguish this specimen from the others Similarly, Baba et al (2009) showed a number of distinct colour morphs of *M. asprosoma* from Taiwan, not dissimilar to the variation reported here, and in some cases different from that of the holotype (Poore et al 2011 pl 16D)

Distribution. Eastern Australia (New South Wales and Queensland), Vanuatu, Taiwan, 495 1802 m Western Australia, 700 1170 m

Munida babai Tirmizi and Javed, 1976

Munida babai Tirmizi and Javed, 1976 81 85, fig 1, 2 (type locality off Natal, South Africa) Baba et al , 2008 88 — McEnnulty et al , 2011 app 1

Material examined Western Australia NMV J55044, 2 males (cl 7 7 mm, pcl 5 1 mm to cl 7 8 mm, pcl 5 3 mm), Ningaloo North, 21° 58 704' S, 113° 49 2' F to 21° 59 052' S, 113° 49 2' F, 170 177 m, SS10 2005 152, 10 December 2005, NMV J55041, 2 males (cl 7 8 mm, pcl 5 3 mm, cl 9 2 mm, pcl 5 9 mm), Ningaloo North, 21° 59.172' S, 113° 49 2' F to 21° 59 79' S, 113° 49 14' F, 165 166 m, SS10 2005 153,

11 December 2005, NMV J55042, 3 females (cl 6.0 mm, pcl 3.8 mm, cl 6.1 mm, pcl 4.0 mm), 4 males (cl 7.7 mm, pcl 5.0 mm, cl 8.1 mm, pcl 5.7 mm), Barrow Island, 20° 59.082' S, 114° 54.42' E to 20° 59.67' S, 114° 54.54' E, 100–101 m, SS10 2005 170, 13 December 2005.

Genetic data. CO1; see Table 1

Remarks. Originally described from off South Africa (off Natal), *M. babai* has subsequently been reported from shelf depths across the Indian Ocean as far east as Hong Kong (Baba, 1988). It can be distinguished by the presence of spines on the anterior margin of abdominal somite 4 and very short supraocular spines. As noted by Baba (1988), the number of spines on the abdominal somites is variable. We found abdominal somite 2 with 5–9 spines, somite 3 with 2–5, and somite 4 with 2–5 spines. The P2 dactylus is 0.75 the length of the propodus in Australian specimens compared to 0.64 for the type (based on Tirmizi and Javed, 1976 fig. 2D), and 0.84 for the Albatross material from Hong Kong and the Phillipines (Baba, 1988). This is the first record of the species from Australia.

Distribution. South Africa, Madagascar, Hong Kong, Malaysia, 70–456 m. Western Australia, 100–177 m.

Munida benguela de Saint Laurent and Macpherson, 1988

Munida benguela de Saint Laurent and Macpherson, 1988: 106, figs 1, 2a, 2c, 3a, 3d, 3f–i (type locality, south of Namibia).—Baba et al., 2008: 89.

Material examined. Western Australia. NMV J56405, 1 male (damaged, cl 11.6 mm, pcl 8.2 mm), SS05 2007 176, Kulumburu L29 transect, 13° 13.482' S 123° 23.742' E to 13° 13.338' S 123° 23.286' E, 392 m, 5 July 2007.

Genetic data. Not available

Remarks. Although this specimen is damaged, most diagnostic characters are evident. In *M. benguela*, the P2 dactylus has 6–8 spines with the ultimate being distant from the unguis. Similarly, our specimen has 8 spines and is unarmed on the distal one third. In *M. benguela*, the fixed finger of the chela has at least 4 spines on the lateral margin which agrees with our specimen. However, our specimen lacks any spines on the mesial margin of the moveable finger while *M. benguela* has a subdistal spine and an additional 2–4 spines on the mesial margin.

Distribution. South African coast between S. Namibia and Natal, and Madagascar; 352–1000 m. North west Australia, 392 m.

Munida compacta Macpherson, 1997

Figure 17A–C

Munida compacta Macpherson, 1997: 605–606, fig. 2 (type locality Kei Islands, Indonesia).—Baba et al., 2008: 90.

Colour. Carapace and abdominal somites 2–4 pale orange-pink. Rostrum red, supraocular spines white or red and white on distal half. P1 pale orange-pink with white fingers, P2–4 pale orange on meri and carpi, white on propodi, dactyli white with red tips.

Genetic data. COI and 16S, see Table 1

Remarks. *Munida compacta* is very close to *M. rubridigitalis* Baba, 1994, and *M. julumunyju* sp. nov. from eastern and western Australia, respectively, and *M. rhodonia*, from New Caledonia. These species can be distinguished by:
· the dactylus of P2 is similar in length (0.8–1.0) to the propodus in *M. compacta* and distinctly shorter (0.8) in *M. rhodonia*
chelipeds with well developed spines on the dorsal face of the palm in *M. compacta*, which are instead very small in *M. rhodonia*.

While the length of the distomesial spine of the P1 merus was used to differentiate these species (Baba, 1997), we found

Figure 17 A, C *Munida compacta* Macpherson 1997 female dorsal view and lateral, NMV 156409) female 18.9 mm pcl 13.4 mm NMV 156990) D *Munida endeavourae* Poore and Ahyong 2004 ovigerous female cl 21.7 mm pcl 13.9 mm NMV 156052 E *Munida gordoae* Macpherson 1994 NMV 156420) Photos K Gowlett Holmes CSIRO

that that the length of this spine varied in our specimens of *M. compacta* and did not always overreach the midlength of the carpus. Also, the P2 dactylus in *M. compacta* is described as clearly shorter than the propodus, but in our specimens, the P2 dactylus was 0.8–1.0 times the propodus length.

The sequences of *M. compacta* from north western Australia and *M. rhodonia* from New Caledonia were 1.2% divergent for COI and 0.2% divergent for 16S.

The present specimens represent the first confirmed records of *M. compacta* from Australia.

Distribution. Indonesia, Kei Islands, 246–694 m. Queensland and Western Australia, 397–470 m.

Munida compressa **Baba, 1988**

Munida compressa Baba, 1988: 91, figs 33, 34 (type locality, Moluccas, Indonesia). — Baba et al., 2008: 91. — Baba et al., 2009: 152, figs 130–134. — Poore et al., 2011: pl. 16H (colour).

Material examined. Western Australia. NMV J55980, 1 male (cl 21.2 mm, pcl 13.0 mm), Kulumburu L29 transect, 13° 13.482' S, 123° 23.742' E to 13° 13.338' S, 123° 23.286' E, 392 m, SS05.2007.176, 5 July 2007; NMV J55981, 4 males (cl 12.0 mm, pcl 8.2 mm, cl 18.6 mm, pcl 12.1 mm), Ashmore L30 transect, 12° 28.884' S, 123° 25.062' E to 12° 29.958' S, 123° 25.002' E, 397–405 m, SS05.2007.189, 6 July 2007.

Genetic data. 16S and COI, see Table 1.

Remarks. This is the first record of the *Munida compressa* from Australia. Sequences from our material and a specimen from the Solomon Islands (Machordom and Macpherson, 2004) were 0.2% divergent for COI and invariant for 16S.

Distribution. Indonesia, Japan, Taiwan, Arafura Sea, 180–668 m. North west Australia, 392–405 m.

Munida distiza **Macpherson, 1994**

Munida distiza Macpherson, 1994: 459, figs 14, 68, 69 (type locality New Caledonia). — Baba et al., 2008: 93. — Macpherson, 2013: 300.

Material examined. NMV J56487, 1 ovigerous female (cl 20.3 mm, pcl 12.6 mm), 1 male (cl 18.7 mm, pcl 12.4 mm), Barrow L1 transect, 21° 00.816' S, 114° 39.15' E to 21° 00.78' S, 114° 38.898' E, 258–271 m, SS05.2007.11, 10 June 2007.

Genetic data. COI and 16S, see Table 1.

Remarks. COI sequences from this material were 4–5% divergent from sequences of *Munida distiza* Macpherson, 1994, from New Caledonia. However, we could not find any distinguishing morphological characters.

Distribution. Philippines, New Caledonia, Loyalty Islands, Matthew and Hunter Islands, French Polynesia, 150–540 m. North west Australia, 258–271 m.

Munida endeavourae **Ahyong and Poore, 2004**

Munida sp. MoV 5199. — Poore et al., 2008: 21, unnumbered figure (lower right). — McEnnulty et al., 2011, app. 1, 2.

Material examined. Western Australia. NMV J55052, 1 ovigerous female (cl 21.7 mm, pcl 13.9 mm), Albany, 35° 26.046' S, 118° 21.06' E to 35° 26.19' S, 118° 20.64' E, 912–922 m, SS10.2005.28, 23 November 2005. Tasmania. MV J59312, 1 specimen, Cascade Plateau, 43° 49.706' S, 150° 29.999' E, 1061 m, TT.01.2008.J2.390.015, 4 January 2009; MV J59310, 1 specimen, Hill off St. Helens, 41° 14.349' S, 148° 49.293' E, 1309 m, TT.01.2008.J2.389.006, 1 January 2009.

Colour. Carapace, abdomen, chela and P2–4 pink. Eggs red.

Genetic data. COI and 16S, see Table 1.

Remarks. Poore et al. (2008) and McEnnulty et al. (2011) recorded *M. endeavourae* from south western Australia as "*Munida* sp. MoV 5199", the present record is the first confirmation of the species from the area.

Distribution. South eastern Australia from south east of Green Cape to Tasmania, 620–1700 m. South western Australia, 912–922 m.

Munida gordoae **Macpherson, 1994**

Figure. 17E

Genetic data. CO1 and 16S, see Table 1

Remarks. *Munida gracilis* is a common species in New Zealand, usually from depths of 300 600 m with a recorded range of about 100 1200 m (Yan et al , 2020), that is morphologically closest to the Australian *Munida chydaea* Ahyong and Poore, 2004. COI sequences of specimens corresponding to *Munida chydaea* Ahyong and Poore, 2004, from south western Australia, however, were only 0 9 1 0% divergent from *M. gracilis* from New Zealand and 0 2% divergent for 16S This low level of sequence divergence led us to further examine the morphological distinctions between *M. gracilis* and *M. chydaea*. Ahyong and Poore (2004) distinguished the two species based on the number of anterior

Figure 18 *Munida gracilis* Henderson, 1885 Variation of P2 dactyli A female cl 32 mm, 18 3 mm, B male cl 26 2 mm, pcl 15 5 mm (NMV J55048), C, ovigerous female, cl 32.3 mm, pcl 18 5 mm (SAM C7658), D, male cl 21 2 mm, pcl 11 9 mm (NMV J53574), E, female, cl 30 0 mm (J53574), F, female cl 23 5 mm, pcl 15 8 mm (NIWA 53772), G, ovigerous female, cl 21 0 mm, pcl 12 2 mm (NIWA 54087)

spines on abdominal somite 3 (1 or 2 spines in *M. chydaea*, 4 spines in *M. gracilis*), the length of the unarmed flexor margin of the P2 dactyli (distal one quarter in *M. chydaea* versus distal one third in *M. gracilis*), spinules on the outer margin of antennal articles 3 and 4 in *M. chydaea* (absent in *M. gracilis*) and more numerous transverse abdominal striae in *M. chydaea*. Our comparisons between new Australian and New Zealand specimens, however, failed to identify consistent distinguishing features. Although the many specimens examined by Ahyong and Poore (2004), primarily from from eastern Australia, were consistent in the aforementioned features, specimens examined herein from southern Australia (Tasmania, South Australia and Western Australia) and New Zealand exhibit morphological overlap. Thus, the shape and armature of the P2 dactyli in southern Australian specimens is variable, with the flexor margin unarmed on the distal one fifth to one third (fig 21A–E). Similar variation was seen in the eight New Zealand specimens we examined; in most specimens, the distal one third of the P2 dactylus was unarmed (fig 21F) but in one ovigerous female (pcl 12.2 mm, NIWA 54087, Fig 21G), the distal one quarter was unarmed. Similarly, abdominal somite 3 is variously armed with 2–4 spines, albeit usually 4 in adult New Zealand specimens, and almost always 2 in adult southern Australian specimens. Another character used to distinguish *M. chydaea* was the presence of outer spinules on the third and fourth antennal article, but such spinules were present on all eight of the specimens of *M. gracilis* we examined from New Zealand. Thus, considered as a whole, Australian material is not reliably morphologically separable from New Zealand specimens, and given the minimal divergence between New Zealand and Western Australian sequences, we consider both populations as probably conspecific.

This brings *Munida disgrega* Baba, 2005, to our attention, which was described from 4 small specimens (cl 10.1–13.0 mm) collected from south eastern Australia and noted as very close to *M. chydaea* and *M. gracilis*. In *M. disgrega*, the flexor margin of the dactylus is unarmed on the distal one quarter to one fifth, which is encompassed by the newly observed variation in *M. gracilis* and *M. chydaea*. Other distinguishing features of *M. disgrega*, such as the length of the chela, the lesser striation and broader anterior margin of the thoracic sternum, and proportionately wider eyes apppear to be allometric differences given the small size of the type specimens. Consequently, we cannot reliably distinguish *M. disgrega* from *M. gracilis* or *M. chydaea*.

Although we do not have molecular data from eastern Australia (type region of *M. chydaea*), on the basis of the low molecular divergence (between New Zealand and south western Australian specimens) and morphological variability within southern Australian specimens that encompasses those from New Zealand and eastern Australia, we regard *M. chydaea* and *M. disgrega* as junior synonyms of *M. gracilis*. *Munida gracilis* is closely related to, but clearly distinct from, *M. haswelli*, with 7.6% divergence in COI and 3.3% in 16S.

Distribution. Southern Australia (Sydney to south western Australia), 146–700 m. New Zealand, 365–610 m.

Munida haswelli Henderson, 1885

Figure 19A

Munida haswelli Henderson, 1885: 411 (type locality off southern New South Wales, Australia). — Baba et al., 2008: 98. — McEnnulty et al., 2011: app. 1, 2. — Farrelly and Ahyong, 2019: 13, 54, fig. 96.

Genetic data. Not available

Remarks. *Munida heteracantha* Ortmann, 1892 has been recorded widely across the western Pacific, including from Queensland, Australia Our specimens show some variation from the lectotype from Japan described by Macpherson and Baba (1993) The lectotype has a pair of small parahepatic spines, which are absent in all our material In most of our specimens the distolateral spine of the basal antennular article is slightly longer than the distomesial spine, while in the lectotype the distal spines are subequal Macpherson and Baba (1993) noted that some specimens of *M. heteracantha* have 2 small median spines on abdominal somite 3, and half of the specimens here have 1 6 spines Only three specimens had the P2 attached, and these show the dactyli with 7 8 spines on the flexor margin, compared to only 5 spines in the lectotype

Munida heteracantha is also similar to *Munida macphersoni* Cabezas, Lin and Chan, 2011, but differs in the length of the supraocular spines, which are very short in *M. heteracantha* (0 34 ∧ rostral length compared to 0 5 in *M. macphersoni*)

Distribution. Japan, Philippines, and Indonesia, off Central Queensland, New Caledonia, Fiji, 100 322 m South western Australia, 170 177 m

Genetic data. COI and 16S, see Table 1.

Remarks. *Munida leagora* was described from New Caledonia, and the present specimens represent the first records of the species from Australia Our specimens show some minor variation compared to the type description, including the presence of 1 or 2 small spines on the lateral margins of the anterior ridge of abdominal somite 2, and the presence of parahepatic spines in some specimens *Munida leagora* is very similar to *Munida alia* Baba, 1994, described from a single specimen in Queensland We compared our specimens of *M. leagora* to the holotype of *M. alia* and confirmed that these species are distinct In Baba's (2005) key to *Munida*, these two species are separated by the length of the distomesial spine of antennal article 1, which reaches the end of article 2 in *M. alia* and reaches or overreaches the distal end of article 3 in *M. leagora*. In addition, *M. alia* lacks a pair of postcervical spines, which are always present in our specimens of *M. leagora*

Divergence in COI sequences between specimens of *M. leagora* from north western Australia and New Caledonia is <0 5% The wide transverse yellow and purple bands on the carapace described for New Caledonian specimens are absent in all the specimens examined here

Distribution. New Caledonia, Loyalty Islands, Chesterfield Islands, Vanuatu, Bayonnaise Bank, Fiji and Tonga, 240 610 m North west Australia, 232 456 m

Munida magniantennulata Baba and Turkay, 1992· 205, figs 2, 3 (type locality Lau Basin) Baba et al , 2008 105 — Farrelly and Ahyong, 2019 13, 54 fig 97

Not *Munida magniantennulata* — Baba, 1994a 12 (*M. typhle* Macpherson, 1994)

Material examined New South Wales NMV J73001, 3 ovigerous females (cl 10 6 mm, pcl 7 2 mm to cl 13 4 mm, pcl 12.5 mm), Central Eastern CMR, 30° 05 862' S, 153° 53 922' E to 30° 07 158' S, 153° 52 47' E, 2429 2518 m, IN2017 v03 086, 5 June 2017

Colour. Carapace, abdomen, cheliped and P2 4 pink Eggs red

Genetic data. Not available

Remarks. The type specimens of *M. magniantennulata* are described as having the P2 dactylus 0 5 0 6 times propodus length, 6 6 times as long as high, and lined with 10 movable spines Our specimens have a very similar P2 dactylus, which is 0 6 0 7 times the propodus length, 5 6 times as long as high, with 9 10 movable spines on the flexor margin The chelipeds of all our specimens lack spines on the outer margin of the fingers or on the dorsal face of the palm, which agrees with the type material All the specimens have two small tubercle like spines on abdominal somite 2

These specimens differ from the holotype in the length of the mesial spine on the first antennal article, which reaches the midlength of article 2 in these specimens but is very short in the holotype

The specimens recorded by Baba (1994) as *M. magniantennulata* from off central Queensland are referred to *Munida typhle* Macpherson 1994 (see *Remarks* for that species)

Distribution. Lau Basin, 1750 2003 m Eastern Australia, 2429 2518 m

Munida aff *Rubiesi* — Poore et al., 2008, 20 (part), unnumbered fig.
Munida MoV 5183 McEnnulty et al, 2011 app 1, 2

Material examined Western Australia NMV J55033, 1 ovigerous female (cl 15.0 mm, pcl 9.4 mm), 31° 36.528' S 114° 58.86' E to 31° 37.038' S 114° 58.26' E, 329 370 m, SS10 2005 06, 19 November 2005, NMV J55035, 1 ovigerous female (cl 15 0 mm, pcl 10 2 mm), near Abrolhos islands, 28° 29 37' S 113° 25 14' E to 28° 30 06' S 113° 25 5' E, 416 431 m, SS10 2005 95, 4 December 2005

Genetic data. Not available

Colour. Carapace and somites 2 4 orange and white, somites 5 6 and telson white Rostrum and supraocular spines orange on base and tips and white in the middle Chela white and orange, and orange red bands on distal half of fingers P2–4 transparent white orange with orange red across the middle of propodus and tips of dactyli

Remarks. The specimens here agree with the lectotype description of *M. militaris* by Baba and Macpherson (1991) *Munida militaris* closely resembles *M. benguela* de Saint Laurent and Macpherson, 1988, but can be distinguished by the following features
moveable finger of the cheliped bears a single basomesial spine
P2 4 dactyli with about 10 ventral spines, the untimate at the base of the unguis
Our specimens differ slightly from the illustrated lectotype material from Fiji and Ambon The lectotype has the distomesial spine of antenna article 2 described as occasionally overreaching the end of the peduncle, while in both our specimens, the distomesial spine distinctly overreaches the distal end of the peduncle

Distribution. Taiwan, Indonesia, Queensland, New Caledonia, Vanuatu, Wallis and Futuna, Fiji, Tonga, 190 1183 m South western Australia, 329 431 m

Munida pectinata Machordom and Macpherson, 2005

Figure 20C

Munida pectinata Machordom and Macpherson, 2005 828, fig 3 (type locality New Caledonia) — Baba, 2008 112 — Komai, 2011 359, fig 10, 11D (colour) (Japan 96 221 m) — Komai, 2012 38 (Izu islands, 174 192 m)

Material examined Western Australia NMV J55268, 4 males (2 damaged, cl 10 8 mm, pcl 6 5 mm, cl 18 4 mm, pcl 10 7 mm), 17° 35 706' S, 118° 58 902' E to 17° 35 346' S, 118° 58 794' E, 108 140 m, SS05 2007 stn 62, 16 June 2007

Colour. Carapace and somites 2 4 pale orange with dark orange markings, somites 5 6 and telson pale orange Rostrum and supraocular spines orange Chela merus pink with red bands, remaining chela mottled orange P2 4 white with orange red bands

Genetic data. COI and 16S, see Table 1

Remarks. These Australian specimens of *M. pectinata* agree well with illustrations of type material from New Caledonia, extending the range to eastern Indian Ocean The north western Australian sequences of COI (639 bp) and 16S were identical to two sequences from New Caledonia This is the first record of *M. pectinata* from Australia

Distribution. New Caledonia, Japan and north western Australia, 96 240 m

Munida pherusa Macpherson and Baba, 1993

Munida pherusa Macpherson and Baba, 1993 408, fig 15 (type, locality Philippines) — Baba et al, 2008 112 — Baba et al, 2009 178, figs 158 159 — Kim et al, 2016 9, fig 9 (Korea, 112 117 m)

Material examined Western Australia NMV J55097, 1 specimen, Ningaloo South, 22° 04 002' S, 113° 48 66' E to 22° 04 248' S, 113° 48 9' E, 101 106 m, SS10 2005 144, 10 December 2005, NMV J13307, 9 ovigerous females (cl 7 7 mm, pcl 4 5 mm to cl 11 4 mm, pcl 7 3 mm), 2 females (cl 8 3 mm, pcl 4 9 mm, cl 9 1 mm, pcl 7 3 mm), 7 males (cl 7 3 mm, pcl 4 9 mm to cl 12 7 mm, pcl 7 7 mm), North west Shelf, between Port Hedland and Dampier, 18° 50' S, 117° 39' E to 18° 50' S, 117° 39' E, 178 m, NWA stn 29, 6 June 1983

Remarks. In addition to one specimen of *M. pherusa* collected in 2005 in north western Australia, another 17 specimens are reported here from a survey of the North West Shelf in 1983 The specimens show that the length of the disto mesial spine on antennal article 2 is slightly variable in length, sometimes just reaching the end of the peduncle and in some specimens, including the holotype, it slightly overreaches the peduncle In the illustrated holotype, the cheliped finger is distinctly shorter that the palm, while in all of our specimens, the cheliped finger and palm are subequal in length
These are the first records of *M. pherusa* from Australia

Distribution. Japan, Philippines, Indonesia, Korea, 73 167 m North western Australia, 101 178 m

Munida philippinensis Macpherson and Baba, 1993

Munida philippinensis Macpherson and Baba, 1993 410, fig 16 (type locality Philippines) — Baba et al, 2008 112

Material examined Western Australia NMV J56003, 4 females (cl 7 9 mm, pcl 4 8 mm to cl 10 1 mm, pcl 9 0 mm), 12 males (cl 7 5 mm, pcl 4 8 mm to cl 11 2 mm, pcl 7 4 mm), Leveque L27, 14° 58 362' S, 121° 38 556' E to 14° 57 762' S, 121° 39 264' E, 228 232 m, SS05 2007 143, 2 July 2007

Genetic data. COI and 16S, see Table 1

Remarks. This is the first record of the species from Australia

Distribution. Philippines, Indonesia, 146 297 m North west Australia, 228 222 m

Munida pilorhyncha Miyake and Baba, 1966

Figure 21

Munida pilorhyncha Miyake and Baba, 1966: 81, figs 1, 2 (type locality: Tosa Bay, Japan). — Baba et al., 2008: 112 (synonymies, type data). — Baba et al., 2009: 180, figs 160–162 (Taiwan).

Munida sp. MoV 5200. — Poore et al., 2008: 20, unnumbered fig. (lower right). — McEnnulty et al., 2011: app. 1, 2.

Material examined. Western Australia: NMV J55145, 1 female (cl 21.5 mm, pcl 16.8 mm), Bunbury, 33° 00.504' S, 114° 34.26' E to 33° 00.12' S, 114° 34.5' E, 414–421 m, SS10.2005.13, 20 November 2005.

Colour. Carapace and somites 2–4 pale orange. Rostrum orange. Supraocular spines white. Cheliped with orange-red spots at base of spines and orange-red at distal ends of chela fingers.

Genetic data. Not available.

Remarks. Poore et al. (2008) and McEnnulty et al. (2011) reported the present specimens as "*Munida* sp. MoV 5200"; this is the first confirmed record of *Munida pilorhyncha* from Australia.

Distribution. Japan, South China Sea, Philippines, Taiwan, Kei Islands, Indonesia, 200–366 m. South-western Australia, 414–421 m.

Munida roshanei Tirmizi, 1966

Figure 20D

Munida roshanei Tirmizi, 1966: 192, fig. 13 (type locality: Gulf of Oman). — Baba, 2008: 116.

Material examined. Western Australia: NMV J55261, 1 male (cl 11.1 mm, pcl 7.2 mm), Barrow L1 transect, 21° 02.148' S, 114° 53.28' E to 21° 01.992' S, 114° 53.142' E, 90–100 m, SS05.2007.8, 10 June 2007, NMV J55991, 16 ovigerous females (cl 8.4 mm, pcl 5.0 mm to cl 10.9 mm, pcl 7.0 mm), 7 females (cl 8.5 mm, pcl 5.3 mm to cl 10.9 mm, pcl 6.7 mm), 22 males (cl 8.4 mm, pcl 4.9 mm to cl 11.2 mm, pcl 6.4 mm), Mermaid L24 transect, 17° 46.104' S, 120° 43.152' E to 17° 45.948' S, 120° 42.942' E, 97–109 m, SS05.2007.97, 20 June 2007, NMV J56400, 2 males (cl 8.9 mm, pcl 5.9 mm, cl 13.5 mm, pcl 8.0 mm), 2 ovigerous females (cl 9.9 mm, pcl 5.6 mm, cl 11.8 mm, pcl 6.8 mm), 3 females (1 damaged, cl 9.5 mm, pcl 5.6 mm to cl 10.0 mm, pcl 5.7 mm), 1 male (cl 8.9 mm, 5.9 mm), Broome L25 transect, 16° 45.156' S, 121° 02.796' E to 16° 44.592' S, 121° 02.208' E, 100–108 m, SS05.2007.116, 30 June 2007, NMV J56009, 2 ovigerous females (cl 10.9 mm, pcl 7.2 mm, cl 11 mm, pcl 7.8 mm), 1 male (cl 7.8 mm, pcl 4.7 mm), Lacepede L26 transect, 15° 48.672' S, 121° 03.738' E to 15° 48.426' S, 121° 03.654' E, 90–107 m, SS05.2007.125, 1 July 2007, NMV J56098, 4 males (cl 8.4 mm, pcl 5.1 mm to cl 11.7 mm, pcl 7.0 mm), 1 female (cl 10.6 mm, pcl 6.7 mm), Adele L28 transect, 14° 33.732' S, 122° 55.092' E to 14° 33.684' S, 122° 54.906' E, 95–105 m, SS05.2007.161, 4 July 2007, NMV J56395, 1 ovigerous female (cl 14.1 mm, pcl 8.6 mm), 1 female (cl 9.1 mm, pcl 5.2 mm), 3 males (cl 11.3 mm, pcl 6.9 mm to cl 11.8 mm, pcl 7.8 mm), Ashmore L30 transect, 12° 26.7' S, 123° 36.048' E to 12° 26.964' S, 123° 36.588' E, 95 m, SS05.2007.188, 6 July 2007, NMV J56007, 1 ovigerous female (cl 11.3 mm, pcl 7.2 mm), 1 female (cl 10.0 mm, pcl 6.3 mm), Ashmore L30 transect, 12° 25.944' S, 123° 35.784' E to 12° 26.064' S, 123° 35.868' E, 111 m, SS05.2007.196, 6 July 2007, NMV J55096, 1 male (missing chelipeds and rostrum, pcl 7.3 mm). Kalbarri, 27° 48.48' S, 113° 17.82' E to 27° 48.756' S, 113° 17.94' E, 112–123 m, SS10.2005.96, 4 December 2005, NMV J55047, 1 ovigerous female (missing chelipeds, cl 11.6, pcl 7.1 mm), 1 male (cl 12.8 mm, pcl 8.0 mm), 1 juvenile (cl 9.0 mm, pcl 5.4 mm), Barrow Island, 21° 01.896' S, 114° 53.52' E to 21° 02.064' S, 114° 53.28' E, 93 m, SS10.2005.169, 13 December 2005, NMV J55045, 1 female (cl 7.0 mm, pcl 5.0 mm), 6 males (cl 8.0 mm, pcl 4.3 mm to cl 12.7 mm, pcl 5.5 mm), Barrow Island, 20° 59.082' S, 114° 54.42' E to 20° 59.67' S, 114° 54.54' E, 100–101 m, SS10.2005.170, 13 December 2005, NMV J55048, 1 male (cl 10.2 mm, pcl 5.8 mm), SS10.2005.170.

Genetic data. COI and 16S, see Table 1.

Remarks. *Munida roshanei* is reported for the first time from Australia. Our specimens have much longer supraocular spines (0.36 times rostrum length) than figured for the type (0.2 times rostrum length) (Tirmizi, 1966: fig. 13). Longer supraocular spines are also present on the specimen from the Red Sea illustrated by Lewinsohn (1969). Our specimens all lack a row of median gastric spines behind the rostrum, whereas the type has a row of 3 median gastric spines behind the rostrum, and in other specimens 1 or 2 spines are reported (Baba, 1988; Tirmizi and Javed, 1993). There is clear sexual dimorphism in this species with males having large, gaping cheliped fingers. All of our specimens have cheliped fingers subequal to the palm in length.

Distribution. Indian Ocean (Gulf of Oman and Gulf of Aden, Red Sea, Andaman Sea and Mozambique Channel), and Phillipines, 16–528 m. Western Australia, 93–123 m.

Munida rubridigitalis Baba, 1994

Figure 22

Genetic data Not available

Remarks *Munida rubridigitalis*, described from Queensland, has been also reported from New South Wales, north western Australia, New Caledonia, Vanuatu, Indonesia (Kei islands) (Macpherson, 1994, 1997, 1999, Ahyong and Poore, 2004, Baba et al., 2008, Poore et al., 2008). The north western Australian records of *M. rubridigitalis* are herein shown to be referable to a separate species, *M. julumunyju* sp. nov., which differs chiefly in having a deeper, more strongly curved rostrum (see account of that species). We compared paratypes and other Australian material of *M. rubridigitalis* to six MNHN specimens identified as *M. rubridigitalis* from New Caledonia (see material listed under *M. julumunyju*). These New Caledonian specimens are herein referred to *M. julumunyju* sp. nov., as are specimens reported from New Caledonia and the Loyalty Islands as *Munida* sp. by Macpherson (1994). Thus, other records of *M. rubridigitalis* from New Caledonia, Kei Islands and Vanuatu could also be referable to *M. julumunyju* sp. nov. (see *Remarks* for that species). At present, *M. rubridigitalis* sensu stricto is known only from eastern Australia.

Distribution. Eastern Australia, from Queensland and New South Wales, 156 549 m

Munida sacksi Macpherson, 1993

Munida sacksi Macpherson, 1993. 438 (part), fig. 6 (type locality Philippines)   Baba et al , 2008 119
Munida sp MoV 5217   Poore et al , 2008 21   McEnnulty et al , 2011 app 1

Material examined Western Australia NMV J55039, 1 male (cl 11 6 mm, pcl 8 2 mm), Ningaloo South, 22° 04.314' S, 113° 45 36' E to 22° 04.854' S, 113° 45 36' E, 387 399 m, SS10 2005.151, 10 December 2005

Genetic data. Not available

Remarks. *Munida sacksi* was described from the Philippines, based on a single female, missing the chelipeds The present specimen, reported by Poore et al (2008) as "*Munida* sp MoV 5217", represents the first record of the species from Australia

Distribution. Philippines, 300 330 m Western Australia, 387 399 m

Munida shaula Macpherson and de Saint Laurent, 2002

Munida shaula Macpherson and de Saint Laurent, 2002 474, figs 3A C, E H [type locality Réunion Island]   Baba et al , 2008 117

Genetic data. Not available

Remarks. The present specimens referred to *M. typhle* were recorded by Baba (1994) from central Queensland as *M. magniantennulata*. These two species are very similar overall, but the cheliped of *M. typhle* has spines present on the dorsal face of the palm and 2 lateral spines on the proximal half of the fixed finger, which are absent in *M. magniantennulata*. In addition, the P2 4 dactyli are longer in *M. typhle* (0 8 times the propodus compared to 0 5 0 6 in *M. magniantennulata*), and abdominal somite 2 has 4 spines on the anterior ridge while *M. magniantennulata* has 2 spines In the Queensland specimens examined here, the P2 dactylus has 7 8 spines along the flexor margin compared to the holotype of *M. typhle*, with 9 spines The QM registration numbers published by Baba (1994) were listed incorrectly and have been corrected here The ovigerous female (NMV J72915, Ahyong and Farrelly, 2019 fig 98) collected during the recent Investigator voyage is much larger than most specimens collected previously This large female differs from other specimens in lacking spines on the cheliped dactylus, and the spines on abdominal somite 2 are proportionally longer (similar in length to the branchial margin spines) and limited to the median part of the anterior ridge

Distribution. Somalia coast, Seychelles, southern Madagascar, Taiwan, New Caledonia, Vanuatu, French Polynesia, 500 1940 m Queensland, 1607 1761 m

Abstract

Sumner, J , Haines, M L , Lawrence, P, Lawrence, J. and Clemann, N. 2021. Phylogenetic placement of a recently discovered population of the threatened alpine she oak skink *Cyclodomorphus praealtus* (Squamata· Scincidae) in Victoria *Memoirs of Museum Victoria* 80 153 157

The alpine she oak skink *Cyclodomorphus praealtus* is a threatened alpine endemic lizard from the mainland of Australia The species is previously known from disjunct populations in Kosciuszko National Park in New South Wales and three isolated localities in the Victorian Alps The New South Wales and Victorian populations represent separate evolutionarily significant units In 2011, a fourth Victorian population was discovered We conducted a phylogenetic analysis and determined that the newly discovered population is discrete and may have been separated from other populations since the end of the last glacial maxima This population requires separate management

Keywords *Cyclodomorphus praealtus*, phylogenetic relationship, conservation, threatened species

Introduction

The alpine she oak skink *Cyclodomorphus praealtus* Shea (1995) is restricted to sky island plains (*sensu* Koumoundouros et al , 2009) above 1500 m elevation in the mainland Australian alpine bioregion (Cogger, 2014) The species has been recorded in New South Wales (NSW) at Kosciuszko National Park and in Victoria at the Bogong High Plains, around Mt Hotham, Mt Higginbotham and Mt Loch, and on the Dargo High Plains at Lankey and Omeo Plains (Clemann, 2011, fig 1) The Victorian sites are all within approximately 30 km of each other (Table 1) The species has specific habitat requirements, occurring in alpine heathland and alpine grassy heathland These habitats generally have a disjunct occurrence and are within a matrix of other alpine and sub alpine habitats in which the alpine she oak skink is not known to occur Within some locations, the species distribution is further fragmented by ski resort buildings and groomed ski slopes, roads and tracks The species is listed as nationally endangered under the federal *Environment Protection & Biodiversity Conservation Act 1999*, threatened in Victoria under that state's *Flora and Fauna Guarantee Act 1988*, critically endangered in Victoria by the Department of Sustainability and Environment (2013) and endangered in NSW under the *Threatened Species Conservation Act 1995*

The species is considered at risk from climate change (Clemann, 2003; Koumoundouros et al., 2009) and is a high priority for conservation management.

Populations of *C. praealtus* in NSW and Victoria are reciprocally monophyletic at the mtDNA ND4 loci, with a 4 28% net sequence divergence between regions, and it was recommended that they be treated as separate evolutionarily significant units (Koumoundouros et al , 2009) The three known Victorian populations exhibit strong genetic structure, with no current inter population gene flow, despite evidence for historical connectivity (Koumoundouros et al , 2009) This concurs with their present disjunct distribution on high elevation plateaux and peaks in alpine meadows that are separated by valleys of eucalypt forests

In 2011, *C. praealtus* was discovered at a fourth Victorian locality the Wellington Plains (Clemann et al , 2016) This is the southern most area where this species has been recorded and is 58 km from the closest Victorian population at Lankey Plain Here we present a phylogenetic analysis to determine the relationship between this new population and those studied by Koumoundouros et al (2009) Our results provide information that will assist the conservation management of this species

Table 1 Divergence among five populations of *Cyclodomorphus praealtus* in Victoria (VIC) and New South Wales (NSW). Uncorrected p-distance (number of base substitutions per site averaged over all sequence pairs between groups, bottom) and straight line distance (km, between locations, top)

	Bogong High Plains VIC	Mt Hotham VIC	Lankey Plain VIC	Wellington Plains VIC	Mt Kosciuszko NSW
Bogong High Plains VIC		31	29	96	101

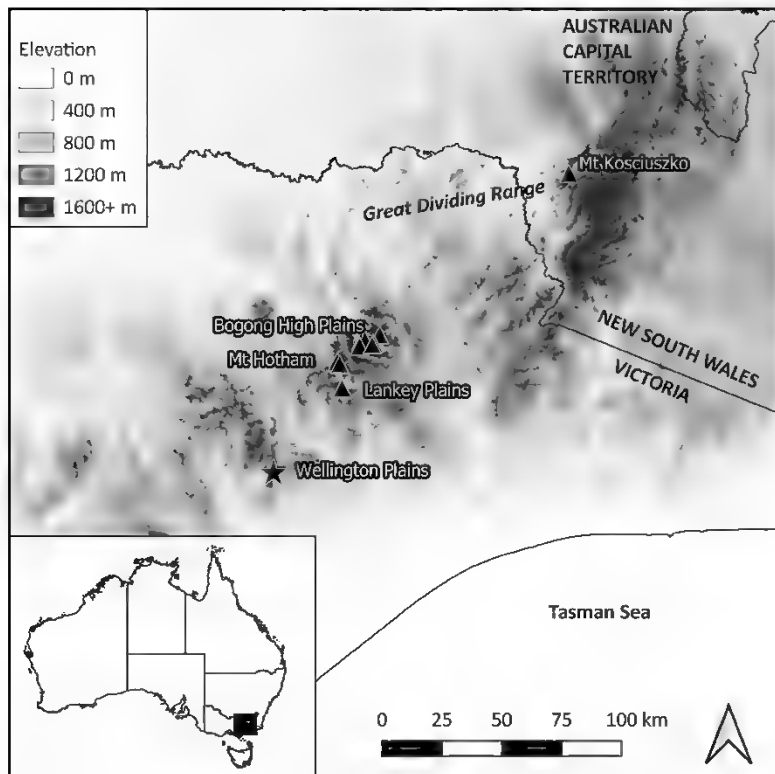

Figure 1 Elevation map of the mainland Australian alpine region indicating the five major populations of *Cyclodomorphus praealtus*, including the new location of Wellington Plains. Elevation is indicated by light, mid and dark grey areas at 500 m intervals, with highest elevations at or above 1500 m above sea level. Adapted from fig. 1, Koumoundouros et al. (2009)

Methods

Discovery of this population of *C. praealtus* and collection of tissue samples is described by Clemann et al. (2016). Tissue samples (tail tips) were collected from two sub adult *C. praealtus* from the Wellington Plains (1530 m elevation, fig 1) in November 2011.

We extracted genomic DNA using a Qiagen DNeasy® Blood and Tissue Kit according to the manufacturer's instructions (www.qiagen.com). An 850 base pair region of the mtDNA NADH dehydrogenase subunit 4 (ND4) gene was chosen for sequencing because it has useful levels of variability in this species and in related skink groups (Chapple and Keogh, 2004; Koumoundouros et al., 2009). ND4 was amplified according to the protocols and conditions in Koumoundouros et al. (2009) using the primer pair ND4I

(5' TGACTACCAAAAGCTCATGTAGAAGC 3'), and tRNA leu (5' TACTTTTACTTGGATTTGCACCA 3', Chapple and Keogh, 2004). The resulting polymerase chain reaction product was purified using ExoSAP IT® (Affymetrix), and the purified products were sent to Macrogen (South Korea) for sequencing.

Forward and reverse sequences were assembled in Geneious R6.18 (Biomatters Ltd.) and were aligned against 103 published sequences and outgroups for this species (Koumoundouros et al., 2009) using default settings in ClustalW. We translated the protein coding regions into amino acids and did not observe stop codons or indels. IUPAC ambiguity codes were used for heterozygous sites. We trimmed the alignments to 758 base pairs because the end of the sequences could not be aligned due to the length variable loops and stems of the tRNA genes. The Wellington Plains sequences were deposited in GenBank.

Figure 2. A Bayesian consensus tree of the mtDNA ND4 sequences, depicting the relationship between unique haplotypes at each locality (Bogong High Plains, Lankey Plain, Mt Hotham, Wellington Plains and Kosciuszko National Park) for *Cyclodomorphus praealtus*. Bayesian posterior probabilities are shown at major nodes.

To determine the relationship of the Wellington Plains population to all other known populations, we created a phylogenetic tree. Only unique haplotypes were used. We used Modeltest 3.7 (Felsenstein, 1985) with the PAUP* plug in run within Geneious R6.18 to determine which of the 56 potential models of DNA sequence evolution was most suitable for our data. The GTR+G model of evolution was selected as the most appropriate model using the Akaike information criterion (Akaike, 1974). The MrBayes version 3.2.6 (Huelsenbeck et al., 2001; Ronquist and Huelsenbeck, 2003) plug in within Geneious R6.18 was used to conduct a Bayesian Markov chain Monte Carlo phylogenetic analysis using two million generations sampled every 500 generations, with four heated chains sampling independently and a 25% burn in. Chain convergence was confirmed by examining the log trace in Geneious and estimated sample size values > 200. The mean between group distance was calculated among all five populations in MEGA6 (Tamura et al., 2006).

To infer the relationship between the mitochondrial ND4 sequences from Wellington Plains and the published haplotypes in Victoria, we created a statistical parsimony network using the program TCS (Clement et al., 2000) using a 95% statistical confidence limit for the maximum number of nucleotide substitutions between two haplotypes.

Results

The ND4 sequences comprised 758 base pairs, including 63 variable sites and 50 parsimony informative sites. The

sequences from the two Wellington Plains individuals were identical and differed from all previously known haplotypes. The Bayesian consensus tree (fig. 2) revealed that the ND4 haplotype from Wellington Plains falls within the monophyletic Victorian lineage and did not group with any other populations. The Wellington Plains haplotype differed from the populations in Victoria by 1.6–1.9% and from the NSW population by 5.9% (Table 1).

A haplotype parsimony network of all ND4 sequences generated in TCS (fig. 3) indicates that the Wellington Plains haplotype forms a third distinct haplogroup cluster, separate from all other Victorian haplotypes, and that they cluster more closely with the north eastern haplogroup that includes individuals from Bogong High Plains and Mt Hotham. Eight nucleotide changes separate the Wellington Plains sample from the closest haplotype from the Bogong High Plains.

Discussion

Analysis of mtDNA ND4 sequences of two *C. praealtus* individuals from Wellington Plains indicates the presence of a haplotype that is not found in any other population across the restricted range of this alpine endemic species. Further work using multiple nuclear genes is needed before we can confirm that the Wellington Plains population is isolated from the other Victorian populations as the current data suggests. It is not possible to determine the level of genetic diversity within the Wellington Plains population due to the small sample size.

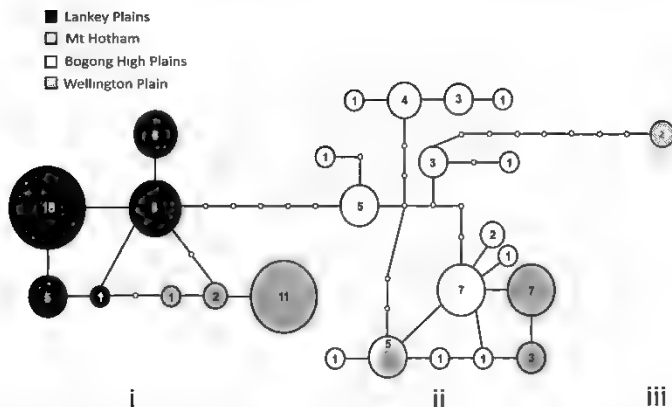

Figure 3. Population structure of Victorian *Cyclodomorphus praealtus* according to ND4 mitochondrial haplotype network. Black indicates individuals from Lankey Plain, dark grey indicates those from Mt Hotham, white indicates those from Bogong High Plains and diagonal stripes indicate those from Wellington Plains. The network structure indicates 3 haplogroups (i, ii and iii) within Victoria. Each circle represents a unique haplotype, with the circle size indicative of frequency and sample sizes within each circle. Empty circles represent missing haplotypes and differ by one base pair from the closest haplotype.

The Wellington Plains population is the most divergent of the populations in Victoria, with 1 6 1 9% sequence divergence from the other populations, compared with the 0 9 1 2% divergence among the other Victorian populations Using the conventional vertebrate mtDNA clock calibration of 2% sequence divergence per million years (Avise, 2004), suggests a divergence time between Wellington Plains and the other populations in Victoria of between 500 000 and one million years before present This places the divergence during the late Pliocene to early Pleistocene, during which climatic oscillations intensified resulting in rapid fluctuation between cool dry and warm wet conditions across south eastern Australia (Markgraf et al , 1995) However, this predates the most recent glacial period from approximately 25 000 18 000 years before present, during which the alpine habitat extended into the valleys connecting the mountain peaks, allowing gene flow between populations of other alpine endemics

In 2019 severe bushfires burned across the entire Wellington Plains plateau and, as a result, the status of this population is now uncertain Surveys to determine whether the population still remains on the Wellington Plains are an urgent priority, both to confirm the status of this population and to identify any other specific threats Threats already identified for *C. praealtus* in the Victorian Alps include climate change, loss and degradation of habitat (due to a range of processes, including several severe fires in the last decade, construction and maintenance of infrastructure and roads, grazing and trampling by exotic herbivores, and recreational activities), and predation by exotic carnivores (Clemann, 2003, 2013) Historically, loss and degradation of the habitat of *C. praealtus* due to cattle grazing also occurred in the Alpine National Park, and damage from this impact remains evident in parts of this lizard's range in Victoria (N Clemann pers obs) Other reptiles endemic to the mainland alpine region also occur on the Wellington Plains, including threatened species such as the alpine bog skink *Pseudemoia cryodroma* and the tussock skink *P. pagenstecheri* The fact that this population of *C. praealtus* remained unknown until so recently demonstrates that further surveys of Victorian alpine environments are needed if we are to document and effectively manage the biodiversity of this region, especially in the face of increasingly frequent and devastating bushfires

The unusual genus *Ramiheithrus* (Trichoptera: Philorheithridae)

Rosalind M. St Clair

Museums Victoria, GPO Box 666, Melbourne VIC 3001. rstclair@museum.vic.gov.au

Abstract   St Clair, R.M. 2021. The unusual genus *Ramiheithrus* (Trichoptera: Philorheithridae). *Memoirs of Museum Victoria* 80: 159–168.

The descriptions of males of the two described species of *Ramiheithrus* (*R. virgatus* Neboiss and *R. kocinus* Neboiss) are expanded using additional material. The female, pupa and larva of *Ramiheithrus virgatus* are described for the first time for the genus. Preliminary genetic barcoding analysis suggests the presence of additional undescribed species that are only known as larvae. The unusual larval habitat is described and issues relating to this are discussed.

Keywords   Australia, groundwater habitat, COI gene, pectinate antennae

Introduction

The genus *Ramiheithrus* was created for two species, one each in Victoria and Tasmania, by Neboiss (1974) with only adult males known at the time. Information here brings the number of species in the genus to four but the two additional species are known only as larvae. The descriptions of males of the two described species are revised here, partly based on specimens from additional sites. Figures indicating differences from the original descriptions, or those showing additional information, are included for males. The adult female, pupa and larva of *Ramiheithrus virgatus* Neboiss are described. The larva of *R. virgatus* is compared with the larvae of two additional species.

The "rami" in *Ramiheithrus* refers to the distinctive pectinate antennae. Pectinate antennae are otherwise unknown in Trichoptera, except for three species of the Odontoceridae genus *Phraepsyche* from South East Asia (Oláh and Johanson, 2010) although the form of the pectination is apparently different. A fossil trichopteran with yet another form of pectination is discussed in Gao et al. (2016).

Few females of Philorheithridae are described and there is variation between species in genera where more than one species is known. *Philorheithrus* now has females of four species described, and these show considerable variation in shape of genitalia (Henderson and Ward, 2006; Mosely and Kimmins, 1954). This suggests that females of other *Ramiheithrus* species may differ from the description below. The vaginal apparatus of *R. virgatus* is illustrated below but there is no information on other Philorheithridae females to compare with.

Larvae of *Ramiheithrus* have very rarely been collected. The few available specimens provide information on variation in the larvae and the likely reason for this rarity.

DNA barcoding data is preliminary but has assisted taxonomic decisions.

Material and methods

The terminology here follows Henderson and Ward (2006) and Holzenthal et al. (2007) but not Neboiss (1974).

All specimens are lodged in the Museum of Victoria (NMV) and have been assigned registration (TRI) numbers. Reared specimens usually include the case with pupal closure membranes and larval sclerites, pupal skin and adult. The adult has not emerged from the pupal skin in some cases and wing venation cannot be discerned. Tissue samples sent to the Barcode of Life Data System (BOLD, http://www.boldsystems.org) for sequencing and analysis have been allocated LTUT numbers. Information on the methods used for sequencing and gene segment sequenced are available on the BOLD website. Data for specimens included in fig. 24 and Table 1 are available from the BOLD website. The neighbour joining tree (fig. 24) was produced on the BOLD website using a Kimura 2 parameter and BOLD aligner (amino acid based HMM) and produced in Newick format using MEGA 7 on 26 October 2019.

Taxonomy

Ramiheithrus **Neboiss**

Type species: *Ramiheithrus virgatus* Neboiss

The information here uses and extends that given by Neboiss (1974).

Diagnosis. This genus is strikingly unique with the antennae of the adult pectinate on the basal half (fig. 1). In males, the superior appendages are fused to segment IX and in basal half to each other to form a hood over the genitalia (figs 2, 3, 22). This is like the hood in *Kosreithrus* and, to a lesser extent, some species of *Aphilorheithrus*. In *Ramiheithrus*, the superior appendages have

the ventral surfaces covered with moderately long spines in the distal third. The inferior appendages are short and very simple, most similar to those of *Kosrheithrus*. As with most Philorheithridae, the forewing has vein R1 joining R2 just before the wing margin in both sexes. However, this join is not present in some specimens in some populations of *R. virgatus* (fig 5) and *R. kocinus* (fig 23) and seems to be absent in at least some species in other genera. The forewing has 0 to 5 crossveins present between Sc and the costa proximal to the level of the r vein in both species, fewer than most *Aphilorheithrus* species but otherwise unusual in the family (fig 5). The hind wing of both sexes with Sc and R1 merged for a short distance before separating and diverging again (fig 5). Spiracles on pleura ventrally on segments 2 to 4 enlarged, elongate and variably fleshy, smaller and more rounded on segments 5 to 8, only lightly sclerotised around them (fig 4).

In the larva, the anterior part of the frontoclypeal apotome is almost twice as wide as posterior to the constriction (figs 10, 24, 26). On the mid leg, the strong dark distal spine on the tibia remains despite the segment being fused with the tarsus (fig 14). This spine is not present in other Australian Philorheithridae genera, although long and short pale setae are often present in this region. The larval case has the posterior opening almost completely closed by larger sand grains and large flat mineral particles but with gaps between these particles (fig 17).

Generic diagnoses are not given for females or pupae because they are known from one species only.

Description. Head pilifers absent, maxillary palps 5 segmented, long and slender in both sexes, labial palps short, about as long as maxillary palps segments one and two combined, antennae about as long as forewing, first segment stout, slightly longer than vertical diameter of eye, second segment very short, next 14 to 16 segments with long lateral branches, becoming shorter on the more distal segments, first 2 or 3 segments may have branched rami (fig 1), a pair of small anterior setal warts near midline, pair of large, elongate, kidney shaped posterior setal warts and pair of posterolateral setal warts encircling posterior half of eye. Thorax 2 pairs of warts on pronotum, most medial pair elevated, 1 pair of rounded scutal warts, usually larger than scutellar warts, male forewing length 9 to 12 mm and lobe on anal margin strongly sclerotised, apex broad apically truncate, forks 1, 2, 3 and 5 present, male hind wing with forks 1, 2, 3 and 5, fork 3 footstalk of variable length. Abdomen a small projection on sternite VII, variable in size.

Male genitalia superior appendages moderately long, deeply excised, very broad and fused basally to segment IX and each other forming a hood, ventral surface of each with short pointed spines covering apical half, segment X (trilobed hood like plate of Neboiss, 1974) trilobed, lateral lobes similar to each other but different to median lobe, inferior appendages a simple short broad plate, sometimes scooped out apically, almost bilobed in some specimens (figs 2, 3, 22). Phallus narrow, tapering apically.

Larva. Final instar about 9 to 12 mm long. Head rounded and somewhat flattened dorsally, strong carinae present just above the eye from the anterior margin to about three quarters head length, forming the lateral margin of the head on each side, region between the carinae sloping ventrally near each

carina which are raised above the head surface, roughened by minute protuberances, antennae very short, close to front of head and below carinae, labrum with 3 pairs of setae at about 3 4 length and another 3 pairs of short stout setae on front margin, lateral two pairs curved along margin, ventral apotome about 1 15 length of ventral ecdysial line; head setation as in fig 10, most setae on the dorsal surface (but not on the carina) are short and very pale usually bent over or lying flat. Thorax metanotum with 3 pairs of sclerites, anteriomedial pair about 4 times as long as posterior pair (figs 11, 24), prosternum with a large posterior central sclerite (figs 12, 25), mesosternum with 2 pairs of closely aligned sclerites medially, smaller and paler than pronotal sclerite, posterior pair rectangular, anterior pair tapering laterally (fig 12), forelegs each with cluster of more than 12 stout black setae centrally on anterior face of femur, all arising from same point (fig 13), tibial spur about 1 3 tarsal length, tarsal claw about half as long as tarsus, apical spine of tarsal claw almost as long as tarsal claw and lying closely along its length, mid leg tarsal claw about 1 5 tibiatarsus, basal spine of claw almost as long as tarsal claw and lying closely along its length, hind legs much longer than forelegs, tarsal claw about half tarsal length, 2 tibial spines on each tibiae about 1 3 tarsal length, 1 on anterior face, 1 ventral, a group of short spines apicoventrally (fig 14). Abdomen tergite IX short, not completely covering the segment, lightly sclerotised, with fringe of about 14 long setae and about 30 short or moderate length setae (fig 15). The lightly sclerotised channel running ventrally from the base of anal claw towards the ventral junction of the prolegs is deeper and more obvious than in some other genera (fig 16). This channel is darkly sclerotised at the deepest point near the base of the anal claw. Anal claws with tooth almost 1 2 length of claw.

Ramiheithrus virgatus Neboiss, 1974:

Figures 1 21

Type Material Holotype male, Victoria McKay Creek, Sassafras Gap, 36° 36' S 147° 47' E, 2 February 1974, A Neboiss (NMV TRI 4558). Paratypes 8 males, collected with holotype (NMV TRI 4559 to 4566).

Other Material examined New South Wales Alpine Creek Kiandra, 35° 52' S 148° 29' E, 20 January 1966, 3 males 2 females (NMV TRI 29289), 16 January 1968, 1 male (NMV TRI 29288), 13 December 1974, 2 males, 3 females (NMV TRI 29290), E F Riek. Victoria Roadside trickles 1 2 km N of Sassafras Gap, 36 6° E 14779° S, 10 February 2010, 1 larva (LT UT720 12) (NMV TRI 54703), D Cartwright and R St Clair, 19 December 2013, 1 larva (NMV TRI 55169), D Cartwright, Roadside seep 1 6 km N of Sassafras Gap, 10 February 2010, 1 larva (NMV TRI 55167), 11 February 2010, preserved assorted dates to 21 February 2010, 3 reared males, 1 reared female, 2 male pupae, 1 female pupa all with larval case and sclerites, 6 larvae (NMV TRI 54806 to 54815), D Cartwright and R St Clair, Whites Bridge Mt Buller Road 5 km SE Mirimbah, 37° 08' S 146° 26' E, 22 Mar 1985, 1 male A Neboiss (NMV TRI 29291), 1 male, 2 Jan 2011, M Shackleton (LT UT723 12) (NMV TRI 54702).

Diagnosis As for the generic diagnosis with the following additions Male genitalia with segment X median lobe elongate, longer than lateral lobes (figs 2, 3).

Larva distinguishable from larvae of the two other species in the genus by the absence of small anterior sclerites on the
Figures 1–4 *Ramphethrus virgatus* male. 1 Sassafras Gap body lateral. 2 Mt Buller genitalia ventral. 3 Kiandra genitalia lateral. 4 Mt Buller abdomen lateral showing elongate spiracles on segments ia = inferior appendage, sa = superior appendage, IX = segment IX, X = segment X

prosternum, the more strongly developed brush of small spines apically on the hind legs (fig. 14) and the reddish brown head and thorax (fig. 11). Collection of additional larval specimens of the two undescribed species may show these larval characters to not be as diagnostic.

Description. Revised after Neboiss (1974). As for the generic description with the following. Antennae rami dark brown, antennal segments yellowish. Forewings irregularly mottled greyish brown, a distinct pale oval spot close to wing margin within fork 3, smaller and less conspicuous ones between the veins above and below it (fig. 1). R1 joins R2 in males and females although R1 joins the wing margin instead in most specimens collected near Kiandra (fig. 5) and a few from Sassafras Gap.

Male genitalia: segment X median lobe laterally compressed, lobe longer than lateral lobes, lateral lobes flat, somewhat truncate in lateral view, phallus comes to a point apically, curved downwards ventrally, inferior appendages somewhat truncate distally in ventral view, irregular or with a concavity (rarely 2) apically in some specimens (figs 2, 3)

Female. Antennal rami on segments 3 to 11, 12, or 13, rami less than half the length of those in males. Forewings with

forks 1 to 5 present, forks 3 and 4 on long footstalks, hind wings similar to male (fig. 5). Sternite VIII with a band of short pale setae along posterior margin (figs 6, 7). Genitalia: tergite IX very broad and sclerotised dorsally, narrowly cleft mesally, medial notch on posterior margin. With a pair of depressions laterally on segment, with a weak carina along dorsal margin of each. Sternite IX with triangular sclerotised area on anterior half of segment, fleshy laterally and posteriorly (figs 6–9). Simple, apical lobes fused with segment X or lost.

Pupa. Head with a pair of prominent rounded, tuberculate warts on the frons taking up most of the width of the frons which are similar to, but more prominent than, those of *Aphilorheithrus* and *Kosrheithrus*, a pair of long setae dorsally medially on the head between the antennae, a second pair just dorsal to the tuberculate warts (fig. 18), labrum with 3 pairs of setae in each dorsolateral corner, mandibles blade like in apical half, narrowing to a point, straight and serrate on inner margin, rounded and smooth on outer margin, with a pair of medium length setae basally (fig. 19), each scape with medium length setae, 1 pair mesal dorsal and 1 pair distal ventral (fig. 18). Legs without swimming fringes, rarely a weak fringe on at least one mid leg. Abdomen with pairs of
Figures 5-9 *Ramneurhrus virgatus* female 5 Kiandra right fore and hind wings 6 Kiandra genitalia latera. 7 Sassafras Gap genitalia latera. 8 Sassafras Gap genitalia dorsal. 9 Sassafras Gap genitalia ventral. d depression
Figures 10–17 *Ramineuthrus virgatus* Sassafras Gap larva. 10 head dorsal. 11 head, thorax and first abdominal segment dorsal. 12 head, thorax and first abdominal segment ventral. 13 foreleg anterior face lateral. 14 legs posterior face lateral. 15 abdominal segment IX dorsal. 16 last abdominal segment ventrolateral. 17 case and posterior closure. cs = cluster of setae. pc = particles closing posterior opening.
Figures 18–21 *Ramsheuhrus virgatus* Sassafras Gap pupa. 18 shed cuticle head and thorax dorsal. 19 anterior of head ventral. 20 shed cuticle abdomen dorsal. 21 last abdominal segment ventral.

anterior dorsal hook plates on segments 3 and 4 each with 2 to 4 teeth, segments 5, 6 and 7 each with 3 to 6 teeth, pair of posterior hook plates on segment 5 each composed of a row of 16 to 25 spines, many bifid (usually different number on each side) covering most of the width of the segment and with a short gap between each plate, spines as long as plates (fig 20). Last abdominal segment elongate subtriangular, with 2 pairs of long setae mesally, ventrally (fig 21). Anal processes as for the family lightly sclerotised, long, very narrow and slightly

curved apically, each with a short dark pigment band close to the apex and without setae (figs 20, 21). Larval case with anterior pupal closure a disc of silk without any openings holding on a capping stone.

Larva As for diagnosis. Final instar larva head capsule width across eyes 1.3 to 1.4 mm.

Remarks Note that the variation found in wing and genitalic structures of the male were found in all populations

Ramiheithrus kocinus Neboiss, 1974.

Figures 22 23

Type Material Holotype male Tasmania Small creek in forest, Corinna. 5 November 1972 A Neboiss and G Kocins (NMV TRI 4567) 1 Paratype collected with holotype (NMV TRI 4568)

Other Material Examined Tasmania Creek crossing Gordon River Road 42 887° S 146 379° E, 11 January 2012, 1 male (LT UT 1103 12) (NMV TRI 54701) M Shackleton and J Mynott

Diagnosis. As for the generic diagnosis with the following additions Male genitalia with segment X median lobe broad, shorter than lateral lobes (fig 22)

Description Revised after Neboiss (1974). As for the generic description with the following Type specimens blackish with faint paler irregular mottling on forewings of which the most conspicuous is a pale area covering cross veins s, r m and m, and extending along back along M1 about half the length of the wing Gordon River Road specimen greyish brown with indistinct white mottling and spots, forewing 9 to 9 5 mm long R2 joining R3 in type specimens only, fork 1 with or without a short footstalk Forewings of male with vein A2 long in type specimens, short in Gordon River Road specimen (fig 23)

Male genitalia Phallus broad apically, segment X lateral lobes with a few moderately long spines medially, inferior appendages come to a slight point laterally (fig 22)

Female, pupa and larva unknown

Remarks This species is known from only two specimens from the type locality and one specimen from a site (Gordon River Road) about 170 km southeast of the type locality DNA information is only available for the southern specimen There is some variation in wing colour and venation and male genitalia but with so few specimens available they are considered conspecific for now

Additional presumed species of *Ramiheithrus*

Larvae found at two localities in the Yarra Ranges National Park are included here and are the only other species known in the larval stage This enables preparation of the generic diagnosis and description The distinctness of these two species is based on the genetic distance, as discussed in the preliminary genetic analysis below

Ramiheithrus sp. 1

Figures 24 25

As for the larval generic diagnosis and description with the following additions

Description. Larval head capsule yellowish brown, width across eyes 1 4 mm, body length 12 mm. The only mid leg on the one specimen has the remnant tibial spine about 1 3 as long as that of *R. virgatus*, prosternum with pair of small sclerites immediately anterior to the large central sclerite (fig 24) These characters may not enable separation from larvae of other species when variation within each species is known *Philorheithrus* larvae also show almost no variation between the three species recognised (Henderson and Ward, 2006)

Material examined Victoria Alderman Creek at Track 32, Yarra Ranges National Park, 37 721° S 145 941° E, 5 November 2009, 1 larva, J. Dean and R. St Clair (LT UT 721 12) (NMV TRI 54435)

Ramiheithrus sp. 2

Figure 26

Description. Adult unknown Larva. As for generic diagnosis and description. Head capsule yellowish brown, width across eyes 1 5 mm, body length 12 mm. Case posterior closure comparatively flat with attached particles smaller and sparser than in the other two species

Material examined Victoria Contentment Creek site FTT4DS R5, CAPIM Black Spur Weir Project, 10 January 2013, 1 larva (LT UT 1385 14) (NMV TRI 55176), Contentment Creek, CAPIM Black Spur Weir Project, 10 January 2015, 1 larva (NMV TRI 54816)

Discussion of COI data

An abbreviated COI taxon identification tree is shown in fig 27 and information on specimens is provided in Table 1. Only one specimen was barcoded from each of five localities. Usually, at least five specimens over the range of the species are required to confirm genetic distinctness. Thus, more sequencing is required to confirm the current interpretation.

The COI taxon identification tree indicates that the two larvae from the Yarra Catchment (LTUT721 12 and LTUT1385 14) are genetically very different from each other and from other specimens (fig 27). Because there is no adult specimen available from either locality, these species are not being formally described.

The genetic distance between the specimen of *Ramiheithrus virgatus* from near the type locality (LTUT720 12) and the specimen from near Mt Buller (LTUT723 12) is close to 5%. This is greater than often considered necessary to indicate distinct species. However, no consistent morphological features were found to support recognition of

the Mt Buller population as a new species. The generally large distances between all specimens indicate that the commonly applied 2% or 3% threshold for species separation may not apply to this genus. As a result, all the Victorian (apart from the larvae from the Yarra catchment) and New South Wales specimens are here assigned to the one species.

Discussion of larval habitat and its implications

Larvae of *Ramiheithrus virgatus* have been collected for the first time. The first larva collected was in a roadside trickle that is only present after rain and which was dry the day following collection. The trickle appeared as a point where a narrow conduit of groundwater reached the surface, rather than just a point where a broad area of groundwater happened to reach the surface. Investigation found pupae and more larvae in saturated coarse gravel behind a large mound of moss. The seep was less than two square metres on a vertical area of road cutting. Water flowed into the roadside ditch from this area in rainy conditions. This locality was very close to

Figure 27 BOLD Taxon identification tree

the type locality and an adult was collected at light at this new locality soon after finding the larvae and pupae. Some pupae were reared to the adult stage. No similar localities were found nearby, despite extensive searching.

After the habitat was recognised, attempts were made to find similar habitats on the Mt Buller Road, the only other locality in Victoria where adults have been collected. No such habitat or *Ramiheithrus* larvae were found. Areas where ground water was flowing into roadside ditches following rain were found but not associated with a particular moss and not appearing to lead to a gravelly conduit. Presumably, such areas are present but not on the roadside, at least at the time of searching. Being so small, such habitats would be extremely difficult to locate hidden within the vegetation.

The only specimen of *Ramiheithrus* sp 1 was collected at a standard riverine habitat. However, as only one larva was collected, despite the site being sampled on numerous occasions by the Environment Protection Authority Victoria over a 20 year period, this clearly is not the preferred habitat of the species. This larva was presumably washed in from its usual habitat. A similar but smaller area of moss was noted on a road cutting about 100 metres uphill from the site but not investigated.

The specimens of *Ramiheithrus* sp 2 were collected from very small trickles, a slightly different habitat to that of *Ramiheithrus* virgatus. Several specimens were collected, therefore, this appears to be their habitat.

The assumption is made that the habitat is similar for all species of *Ramiheithrus*. The fact that only a single larva has been found in a true riverine habitat supports the fact that the main habitat is unusual, and soaks like that where *R. virgatus* was collected near Sassafras Gap are considered the most likely.

Although found in alpine areas, this genus has not been found above 1500 metres. This also could be related to the habitat as it would occur lower down the mountain where ground water seeps out of conduits and associated with a particular type of moss.

The fact that collection of the larvae is so difficult means that species in this genus will be difficult to manage. *Ramiheithrus virgatus* is listed as vulnerable in Victoria and *R. kocinus* is listed as threatened in Tasmania. The adults are rarely found and in low numbers when they are collected. However, E Riek collected adults at the one locality four times over 11 years. Adult specimens have been collected from the White Bridge locality on more than one occasion, although collecting on other occasions was unsuccessful. It is possible that adults usually remain near the larval habitat. Targeted collecting would be extremely difficult due to the very patchy nature of the habitat.

With the larvae and adults probably living in small areas of habitat spread over a wide area, could this be the reason why adults have rami bearing antennae. Presumably they have a sensory function. Gao et al. (2016) suggested rami enable greater sensory function for detection of pheromones or volatile chemicals from food. It is possible the rami in *Ramiheithrus* are used to locate other adults in highly localised habitat patches.

The absence of swimming fringes on the mid legs of the pupae may be an adaptation to the larval habitat as the pupae were not collected in free water. At this stage, the pupa of only one species is known so this may not be typical of all *Ramiheithrus* pupae. Examination of pupae from most Australian Philorheithridae genera found they have swimming fringes. One of the two species of Philorheithridae pupae described from New Zealand, *Philorheithrus agilis* is found in swift streams has swimming fringes while *Philorheithrus litoralis* has a very weak fringe of few pale setae and is found in small streams or seepages (Henderson and Ward, 2006).

Two females of *Ramiheithrus virgatus* reared from pupae had many well developed eggs in the abdomen. This may be another adaptation to the unusual habitat, but because it is not known how many philorheithrid species are similarly advanced when emerging, this cannot be confirmed.

Abstract   Coleman, D 2021 George Lyell and Frederick Parkhurst Dodd: authority and expertise in nineteenth century Australian entomology *Memoirs of Museum Victoria* 80, 169 181

This article focuses on the correspondence and careers of two lepidopterists, George Lyell and F. P. Dodd. Drawing on Dodd's unpublished letters to Lyell during the late nineteenth century rage for butterflying, it examines how private acquisition gave way to the professional activity of collecting and, in Lyell's case, the eventual gifting of a large and significant collection of moths and butterflies to the National Museum of Victoria from 1932 through to 1946. The article also examines how issues of authority and expertise were measured and contested among collectors in this period.

Keywords   F. P. Dodd, George Lyell, lepidoptery, collecting, correspondence, professionalisation, National Museum of Victoria

Introduction

Professionalisation in nineteenth century life sciences is a lively topic within British and North American histories of science, but it is a topic less examined in the Australian context This article extends current debates by examining the correspondence between two self taught Australian lepidopterists, Frederick Parkhurst Dodd (1861 1937) and George Lyell (1866 1951) Both were private collectors, born in the shadow of the Grampians in south west Victoria, but that is where the similarities end Lyell built a large collection of Lepidoptera while working full time in business, whereas Dodd supported a large family through selling his specimens The article begins with Lyell's decision in 1932 to donate his large collection to the National Museum of Victoria It then moves back in time to an examination of Dodd's letters to Lyell from 1897 1904 These letters, while reflecting informal one to one transactions of exchange, donation and purchase, operate within a much larger push and pull of external factors These external factors include a wide network of people who were themselves subject to a thicket of protocols, depending on their perceived status within the group Furthermore, the complexity and interdependence of the various people involved in the science of entomology led to many disputes about who exactly qualified as professionals Arguments as to who held the most requisite authority and expertise were particularly acute during what has been dubbed the Period of the Amateurs, 1890 1930 (Mackerras, 1949)

The George Lyell collection

In March 1946, Richard Pescott (1905 1986), Director of the National Museum of Victoria, informed the Australian Broadcasting Corporation's Melbourne office that the first instalment of a magnificent collection of Australian butterflies and moths was about to be exhibited in the main hall of the museum on Russell Street The collector was George Lyell (1866 1951, fig 1), and his gift to the museum was so large that it had to be exhibited in relays, from 1 April 1946 until mid year The announcement contained an overall description of the collection as well as information gleaned from an interview with Lyell about his gift to the state of Victoria Although the whole appeared under Pescott's name, the real author was journalist and naturalist Charles Barrett (1879 1959) After the Australian Broadcasting Corporation published the piece, Barrett then circulated it to *The Herald*, *The Sun*, *The Age* and *The Argus*

We learn from Barrett's interview that Lyell had decided to donate his collection after suffering a serious illness in 1932 In the 14 years since then, he had devoted himself to the colossal task of preparing more than 50 000 individual specimens for the handover, remounting and resetting many of them in the process His aim was to build for the museum "the most comprehensive collection of Australian moths and butterflies ever known". At the time of Barrett's writing, the collection numbered 51 216 specimens, consisting of 11 721 butterflies and 39 495 moths, representing 6177 species all told. World renowned authorities had already named 534 type

specimens, but new species were still being discovered and named within the collection. In addition to praising Lyell's great scientific knowledge and technical skill, Barrett emphasised that the gift had been unconditional, Lyell having taken the "broadminded scientific view" to amalgamate the Museum's collection with his own. In this way, gaps would be filled, ensuring that the collection would be "truly representative of Australian entomology". Barrett concluded with a brief overview of the collection's highlights, such as the "particularly beautiful" swallowtail butterflies and the "lovely Blue butterfly, *Papilio ulysses*". It was in the moths, however,

that the collection approached perfection (Melbourne Museum, Notice to Manager, ABC, AB 576, 29 March 1946).

Lyell was born at Ararat, Victoria, in 1866, the fourth of eight children (Hewish, 2014). His father was a printer born in Scotland and his mother was English. Apparently, he showed little interest in natural history until he caught his first butterfly, a caper white, at Albert Park in 1888. Wanting to know more about this creature, the 22 year old contacted Frank Spry (1858–1922) who immediately introduced him to the Field Naturalists' Club of Victoria, which was founded in 1880. While attending meetings regularly over the course of

Figure 1. George Lyell as a young man

the following year, Lyell continued to collect at Albert Park, where he distinguished himself by collecting 13 lesser wanderers, a butterfly that had not been recorded in southern Victoria for well over a decade He also made occasional visits to other well known hunting grounds Murrumbeena, Springvale, Hampton and Cheltenham

In 1890, Lyell moved to Gisborne in central Victoria to work as bookkeeper for the town's largest business, Cherry & Sons Pty Ltd, timber merchants and manufacturers of dairy equipment Later, as Lyell rose to Manager and then Director, the firm developed an export business in entomological supplies such as nets, mounting boards, pins, forceps, cotton wool, boxes and cabinets (Hewish, 2014) Here, in this small country town outside Melbourne, Lyell lived for the rest of his life His collecting was confined to Victoria and New South Wales, except for one trip each to South Australia, Tasmania and southern Queensland Nevertheless, he corresponded and exchanged Australia wide with scores of notable entomologists such as A J Turner and R Illidge of Brisbane, G M Goldfinch of Sydney, G B Lower of Adelaide and F P Dodd of Kuranda, north Queensland He also co authored, with G A Waterhouse, *The Butterflies of Australia* (1914) This extensive exchange network across Australia resulted in long series of individual species, a notable and highly valuable scientific feature of Lyell's collection

In outlining Lyell's career, Barrett paid particular attention to Lyell's triumph over the largest obstacles facing collectors, namely housing his collection and protecting it from the scourges of pest infestation and mould Lyell achieved this by devising a small display cabinet of six or eight drawers, constructing it in such a way that each subsequent unit could be fitted together to make more cabinets, similar to the way in which a bookcase might be enlarged In the 1890s, at the start of his collecting career, Lyell could only afford to build one of these cabinets annually, but by 1932 he owned more than fifty, built by Cherry & Sons What Barrett did not know, or chose not to disclose, was that Lyell had approached Sir Macpherson Robertson in 1934 for £500 to build the many extra cabinets he needed to house his gift Robertson, founder of the MacRobertson Confectionery Company in the Melbourne inner city suburb of Fitzroy, was one of Australia's richest and most successful businessmen Whereas Cherry & Sons struggled after the Depression, business remained strong for Robertson who contributed generously to the upcoming centenary of Melbourne's founding in 1835, including a substantial donation towards the building of the city's herbarium In essence, Lyell asked Robertson to do for Australian Lepidoptera what he had recently done for botany Signing off anonymously as a collector and fellow Scot, the normally modest Lyell took the opportunity to boast that his collection would be "an object lesson to all the museums of the world and a lasting scientific attraction to Melbourne" Lyell finished by inviting Robertson to make enquiries of the Museum Director, D J Mahony, an invitation promptly taken up by the confectionary magnate (Melbourne Museum, Archive Box 579, 27 December 1934) In his response, Mahony revealed Lyell's identity and confirmed that a shortage of money was indeed hampering the progress of his gift In

praising the collection as "the best of its kind", Mahony described the meticulous way in which Lyell cared for his insects Not only did he perform yearly stocktakes to check on their condition, he also compiled annual balance sheets showing acquisitions, as well as insects discarded or exchanged Mahony confirmed that "Every specimen is therefore fully documented" (Melbourne Museum, Archive Box 579, 9 January 1935) In the end, Robertson declined to support Lyell, arguing that he had already over committed himself in support of the city's centenary

George Lyell and Frederick Parkhurst Dodd

When interviewing the elderly Lyell in 1945, Barrett asked him which was the favourite of his 6177 insect species Lyell at first parried the query, declaring "you <u>have</u> set me a poser They are all beautiful", In the end he confessed that it was the Queensland wood moth *Dudgeonea actinias* Turner, bred "from a rotting log in a creek bed at Townsville" by Frederick Parkhurst Dodd (fig 2) In 1903, Cyclone Leonta buried the log under 30 feet of flood debris Of the 13 specimens bred by Dodd, seven are in the Lyell collection (fig 3) While Dodd was just one of Lyell's many Australian correspondents, we know a lot about their relationship because there is an extensive run of letters from Dodd to Lyell in the Melbourne Museum archive Although, unfortunately, Lyell's letters to Dodd do not appear to have survived, the correspondence reveals the many interdependent players and complex processes at work in shaping the Australian entomological community during the late nineteenth century

The collecting, exchanging and selling of insects was serious business in the years leading up to Australian Federation in 1901, evident in the brisk and lively circulation, both locally and internationally, of collectors, publications, specimen boxes and letters Given the enthusiasm for Lepidoptera, there was serious money to be made, especially on large and brightly coloured tropical specimens The story of Conrad Kelsall, an English immigrant farmer who settled in the rainforest of north Queensland, is instructive Within four short months in 1903, we see the rise and fall of Kelsall's hopes for a tidy profit from butterflying on the Little Mulgrave River In letters to his sisters back in Devon, he began with great confidence, declaring his tropical home as "so new & unexplored that one is almost certain of making new finds" With the help of an indigenous man nicknamed Paddy, who captured about a dozen males of the large birdwing butterfly *Ornithoptera euphorion* Gray, Kelsall asked 6d for each of them from Alfred Bell, an insurance agent and butterfly enthusiast based in Cairns Later, for a box of 100 butterflies, Bell paid Kelsall 25 , proposing that, instead of cash transactions, his profit would double if he agreed in future to "run on halves" and "take some risks" Once the business was "in full swing", Bell envisaged that similar boxes might average out at "£3 or £4 per hundred" Although new to the collecting business, Bell boasted international contacts with the famous lepidopterist Walter Rothschild, as well as with Watkins and Doncaster, the English natural history dealers Bell was also supplying insects to Lyell and Waterhouse in Sydney, at that time preparing their catalogue of Australian butterflies But within a few months, Kelsall confessed to his sisters that he

and his business partner needed "to modify our castles considerably" After failing to catch anything in an expedition to Lake Barrine, they returned to discover that all but 14 of the 100 insects they had sent to the Australian Museum had been rejected. Worse was to come in the shape of an insulting and caddish letter from the English dealers who purchased only two of the butterflies sent over. Claiming that the rest were too damaged, they promised to return them all to Queensland but no box arrived, leaving Kelsall to conclude, ruefully, that "it is easy swindling a person 12 000 miles away" (Lambkin, 2013).

While Kelsall was one of many minor part time enthusiasts, Frederick Parkhurst Dodd is now regarded as a leading Queensland collector. Born in Wickliffe, Victoria, one stagecoach stop from Lyell's birthplace in Ararat, he was the son of a pound keeper and the eldest of eight children (Monteith, 1991; Neboiss, 1986). After the family moved to Stawell, on the edge of the Mallee, Dodd was educated at the same local state school as Lyell. Here the similarities stop. While Lyell went on to lead a settled life in a rural town within easy reach of Melbourne, Dodd joined the bank in Victoria and was then shunted around to various bank jobs in Queensland, starting in remote Townsville in 1884. He never returned to live in Victoria. Apart from six years in Brisbane, where he met and learned much from a number of prominent entomologists connected to the Queensland Museum and the Natural History

Society, Dodd's early life as a bank clerk took place a long way from the metropolitan scientific societies of Brisbane, Melbourne and Sydney. Eventually, hating the confinement of office work, and determined to become a full time collector, he left the bank and eventually settled in 1904 in Kuranda, a tiny town on the Atherton Tableland. The area was rich in insects, but all his entomological books and journals had been destroyed by Townsville's Cyclone Leonta the year before. In Kuranda there were no local libraries and no entomological societies or meetings in which he could participate.

In Dodd's letters to Lyell, we see the value, and indeed the necessity, of correspondence that connected him to Melbourne's scientific and collecting community, including the Victorian Field Naturalists' Club and the National Museum of Victoria. Lyell kept Dodd connected to professional societies and their activities, including access to the all important journals. Membership of these societies and subscriptions to their publications were expensive, often beyond Dodd's means, but when business was good, he turned to Lyell for suggestions as to who might propose and second his admission. In addition to Waterhouse and other prominent entomologists at the Australian Museum in Sydney, Lyell counted Walter Froggatt (1858–1937) as a friend. Founder of the Naturalists' Society of New South Wales in 1891, Froggatt published regularly on Australian entomology in

Figure 2. *Dudgeonea actinias* Turner

Figure 3 Seven specimens of *Dudgeonea actinias* Turner

the *Proceedings of the Linnean Society of New South Wales* After Froggatt was appointed government entomologist to the New South Wales Agricultural Department in 1896, Dodd asked Lyell to mention him in case the Department wanted to purchase some of his specimens (Museums Victoria Archives, OLDERSYSTEM~03023, AB 00368, 24 March 1901)

Dodd's correspondence with Lyell is rich in self description, shedding light on the so called divide between mere collectors and entomologists The label of mere collector had been hurled by Gerard Krefft, controversial Curator of the Australian Museum, at William John Macleay during a parliamentary investigation into the museum in 1874 (Ville, Wright, and Philp, 2020) Although this divide between the true scientist and the mere collector was more rhetorical than real, it was deeply embedded in nineteenth century thinking about who exactly possessed the authority and expertise to speak for entomology In 1838, the British entomologist John Obadiah Westwood (1805 1893) described as the very "lowest class of entomologists" those "whose sole object is the procuring, either by capture or by purchase, of a collection of handsome insects, to be placed in drawers without any arrangement other than that of beauty and colour or size" (Wale, 2019, pp 405 406) As an insect breeder and naturalist, Dodd was far from this lowest class His deep knowledge of the bush around him and pride in his technical skills are clear in his letters, which are full of observations about the habits and life histories of insects their location and distribution, their food plants, their relationship to other species and genera, their enemies and their mechanisms for self defence Many of Dodd's fine grained observations stemmed from tireless watching of the insects with which he lived intimately, both at home in breeding boxes, in the bush beyond, and in his Kuranda garden, planted with especially chosen flower and tree species

Despite his expertise, it is notable that Dodd never describes himself as an entomologist. Instead, his insects are "entomological material" and he himself is a "worker in Entomology" He even apologised to Lyell in his first letter for addressing him as entomologist on the envelope, explaining that he wanted to ensure the letter reached him (December 1897) There are several explanations for why Dodd refused to call himself, or anyone else he admired, an entomologist The first reason was his dislike of the entomological fraternity "I have a very poor opinion of Entomologists generally", he tells Lyell In particular, he had little time for the growing number of sedentary and salaried museum men whom he regarded as far less knowledgeable and skilful than himself Writing to Lyell in 1901 about J A Kershaw (1866 1946), later curator and then Director of the National Museum of Victoria, Dodd places him contemptuously amongst the "amateur Entomologists", with the word "amateur" doubly underlined for emphasis (National Museum of Victoria, 15 July 1901) The reason for his dismissal of Kershaw and others stemmed from his pride as an insect breeder with first hand eye witness experience Even Froggatt, author of *Australian Insects* (1907), the first comprehensive textbook on Australian entomology, failed to come up to scratch in Dodd's opinion While he conceded to Lyell that Froggatt "may be a good entomologist" he added that "he had better drop writing the life histories of moths" According to Dodd,

Froggatt had been duped by a Newcastle collector called Thornton into believing that the larvae of *Endoxyla encalypti* had bored as deep as five feet into the wattle tree roots, "high class rubbish" that had been published in the *Proceedings of the Linnean Society of New South Wales* (National Museum of Victoria, 1 January 1898) Elsewhere, Dodd refers to Froggatt (anonymously) as "an Australian Munchhausen" for producing the same exaggerated observations (Dodd, 1916)

Keen to read the latest essays, notes, and pamphlets about insects, Dodd published some important discoveries of his own in entomological and natural history journals, both Australian and international Geoff Monteith gives two examples of the ways in which Dodd was ahead of his time in understanding the life histories of insects Dodd is now known for his breakthrough insights into the symbiosis between green tree ants and the highly prized butterfly *Liphyra brassolis* Westwood Also notable was his detection of the mimicry between the rare swallowtail butterfly, *Papilio laglaizei* Depuiset, and the poisonous day flying moth, *Alcides agathyrsus* Kirsch (Monteith, 1991) However, with no access to large reference collections and short on time, Dodd was, as he confessed to Lyell, "but poorly acquainted with the names of our [Australian] insects" (National Museum of Victoria, 11 October 1897) A few months later, having picked up on the fact that Lyell was "well posted in the names", he asked him for help, confessing that

> unfortunately hundreds of my species are yet unknown to me by name, I shall do all I can to get them identified + hope to get a list compiled such as yours When furnishing particulars of specimens sent, or even acknowledging exchanges, can you kindly add names of sub family + family of individual specimens, in many cases the generic name + view of the moth does not tell me what the insect is (National Museum of Victoria, 11 December 1897)

Before long, he was thanking Lyell for the trouble he had taken in supplying him with names (National Museum of Victoria, 12 February 1898)

Dodd's failure to master the precise names of insects did not mean that he despised the systematists In fact, he was extremely proud of the great attention shown to his collection by Brisbane based Dr Alfred Jefferis Turner (1861 1947), an expert in classification who would often travel to Townsville, and later Kuranda, to study, describe and name Dodd's insects (National Museum of Victoria, 29 September 1900) You can hear Dodd's pride in a comment he made to Lyell of a small syntomid he sent on to him Turner, he wrote, regarded the specimen "as a great prize, and in fact he thinks very favourably of all the kinds I am sending you He often calls upon me, to examine my collections, + learn if I have anything fresh in the way of captures, or from my breeding boxes" Rowland Illidge, Dodd's mentor during his years in Brisbane, was another expert identifier, helping him to name hundreds of species Despite his self confessed deficiencies in this arena, Dodd was never cowed When Lyell returned a large hawk moth, believing it was not the moth Dodd had promised

him, Dodd exploded with irritation. In this instance, where the differences between species were scarcely perceptible, Dodd's experience as a breeder gave him that extra degree of self certainty (National Museum of Victoria, 27 May 1901)

On balance, rarity was a strong possibility in the remote Queensland tropics, but how could Dodd always be certain, lacking expert associates and reference materials? Perhaps his rare insects were common elsewhere? Furthermore, in several letters, responding to Lyell's doubts about identifying a particular specimen, Dodd asked him to "refrain from getting fresh species named" until he had corresponded with Turner on the matter. If the insect was indeed rare, Dodd could only get full credit for the discovery after Turner's identification. More often, to his regret and frustration, he confessed to Lyell that he

> carelessly sent away unnamed things, perhaps some reared with great care + trouble, to find some day that they have been described from "Somebody" collection, having been taken or bred in Queensland!! This is very annoying to me I have bred more Zeuzeridae than anyone living or dead, and my name is never mentioned in connection with the new things Also I have bred more Charagiae [*Aenetus*] than anyone else As to Xylos I have bred over 50 species in north Q'land, including those I got at Charters Towers years ago, perhaps 60 species I don't know how many species I bred in south Q'land (National Museum of Victoria, 26 November 1900)

Clearly, Dodd resented the anonymity that came with living so far away from the centres of entomological research. Given the toil of collecting rare and elusive insects, this was understandable. Why should others, often wealthy purchasers, be given the credit for his work? This sometimes made him quite vain about being acknowledged for the discoveries he had made. In a letter of June 1898, he followed up with Lyell on one of his moths "Oh, when getting that beautiful Oecophoridae named did you credit me with breeding it? I have <u>one</u> left and Dr Turner was charmed with it" (National Museum of Victoria, 9 June 1898) At other times, however, he begged Lyell to conceal information about what and where he was collecting. The wish to be acknowledged for the very details he needed to conceal reveals the painful bind in which he found himself (Monteith, personal communication, 6 July 2018)

Lyell understood his correspondent's dilemma and was happy to observe the friendly protocol of sending all queries about names to Turner before consulting anyone else. In return, Dodd made a point of impressing on Lyell how much he trusted him. For instance, Dr Turner was, he told Lyell, anxious to name one of his insects as new but he only had two specimens, one of which he had sent to Lyell "No other collector would have done that", he declared. Nevertheless, Dodd's inability to name insects scientifically remained something of a sore point, leading him many years later to pronounce, defensively, to J. A. Kershaw

> It is too severe a <u>mental strain</u> for a professional collector to attempt to learn the names of the

> thousands of insects which pass through his hands, so I seldom can supply names   . Years ago I had a long list of names of Lepidoptera, but lost it in the Townsville cyclone I could not replace it, a busy life of collecting has prevented my endeavouring to make another

Dodd's boast was that he possessed other skills, such as his detective work in locating and hatching out insects, then setting them perfectly, reminding Kershaw at the end of his letter "I can send nicely set bugs ants &c &c if the Mus[eum] cares for same" (National Museum of Victoria, 1 June 1911)

Building Trust

Dodd's first letter to Lyell, dated 9 September 1897, enquired if he might be included in his circle of "exchanging correspondents" (National Museum of Victoria, 9 September 1897) Dodd had often seen Lyell's "nicely set insects . perfect in every way" in Queensland, so he was confident that their exchanges would not just be rewarding but (even more importantly) equal A perfectionist, Dodd often complained about the low standards of others In fact, he told Lyell he did not want Melbourne entomologists to know that he had a large number of insects for exchange, his reason being that "several of them do not set well enough to please me + as a rule I get inferior material to my own" Kershaw, for instance, had proved disappointing, palming off on him "faded, damaged, or common specimens" for the "rare or beautiful things" he had been sent Lyell was probably sympathetic, like Dodd, he was proud of his meticulous standards of preservation and mounting Notably, although Barrett would later describe Lyell's gift to the National Museum as unconditional, there was, in fact, one condition When it came to amalgamating his collection with the Museum's, Lyell stipulated that his own was to take precedence While anything worth saving from "the smaller and poorer old museum collection" would be remounted for inclusion, he demanded that most of the museum's specimens be scrapped (Melbourne Museum, Archive Box 579, 27 December 1934, Lyell to Robertson)

Despite Lyell's meticulously high standards, Dodd soon found cause to chastise him for the arrival of 26 damaged specimens, including some with "one or both antennae broken and missing". Suddenly, the mutual trust and reciprocity that was to cement their relationship was threatened. The geographical balance and complementarity that Dodd was seeking between Victorian and Queensland specimens was also jeopardised

> In looking through the exchange lately received I regret to notice that many of the specimens are imperfect, or rubbed, and others seem rather old You may remember my request for clean and perfect insects, and I trust future lots will be a great improvement on this   I have a large collection and the condition of same is first class I keep no damaged specimens that I can replace with perfect ones and I am sorry to say that my Victorian collection compares very

poorly with my own; in fact they spoil the appearance of the others Therefore I want no more damaged things and no matter how rare a species is, please do not send it to me unless perfect in every particular I cannot prize a thing with a great gap or gaps in its wings, antennae missing, or badly rubbed &c &c Should you care to continue these exchanges may I hope that you will kindly place me upon your first class list ... (National Museum of Victoria, 12 February 1898)

Behind Dodd's fastidiousness lay the fear that Lyell was not taking him seriously enough. Perhaps Lyell regarded him as a mere collector? This anxiety is evident in the way in which the adjective *first class* shifts in this paragraph, from the insects in Dodd's collection to the list of Lyell's correspondents Keen to reinforce his standing as a first class collector with a first class collection, he reminded his Melbourne correspondent of the abundance he enjoyed as a tropical collector Unlike many who were obliged to capture "almost everything that flies", he had the geographical advantage of refusing hundreds when out in the fields The spectre of being branded as a mere collector, isolated from professional networks, also prompted Dodd to say that, should anyone enquire of a particular insect, then

perhaps you will have it mentioned they are in collections Lyell et Dodd, not taken by me as if I was a mere collector I fear there is an impression abroad that I want specimens for others and not myself and that that is why I "haggle" for only first class specimens, should therefore you have any such impression pray dismiss it

In other words, Dodd wanted it to be known that, instead of collecting insects solely for exchange, he was proud to retain many of the most perfect and beautiful insects for his own collection (National Museum of Victoria, 16 July 1898)

This early rupture was soon healed when Dodd received a parcel whose contents were "perfect in every way" Writing to thank him, Dodd made no apology for being fastidious In fact, as if to underline the absence of any apology, he added bluntly that Lyell's new parcel contained "several common things" he did not want These he would return straight away Unable to resist reiterating the point about tropical abundance, he had to concede, in fairness, that he was able to catch more in 24 hours than Lyell could catch in five days, but that discrepancy did not mean he had to accept "poor or broken things from a Victorian collector". Nevertheless, the relationship was important to him so that meant an on going commitment to the delicate task of building trust and reliability. When Lyell received a rare and expensive butterfly, *Ogyris genoveva* Hewitson, and one of its antennae was missing, Dodd insisted that the specimen was absolutely perfect when despatched from Cairns, nevertheless, he immediately sent a damaged specimen with "one good antenna to replace the lost one" (National Museum of Victoria, 26 October 1900, 26 November 1901) As part of the

rules governing their exchange, Dodd also assured Lyell that he could return anything he did not want for credit

This gentlemanly exchange of first class specimens continued for another couple of years until August 1900 when Dodd informed Lyell that altered circumstances meant he was unable to continue indulging in this pleasurable pastime With a growing family and a costly relocation from Brisbane to Townsville   a place of "higher prices for everything"   he must now leave off his gentlemanly pursuits (National Museum of Victoria, 27 August 1900) To Kershaw, whom he hoped would purchase insects for the National Museum of Victoria, he wrote that instead of gracing his friends' cabinets, he must now look upon his "beloved specimens   from an £8 point of view" "Most of my best things are reared", he boasted, adding "I keep no rubbish, and no one need fear at any time that I will victimize my correspondents" Despite the taint of trade   making dollars

Dodd nevertheless insisted that his business was an honourable calling Furthermore, he would keep himself at arm's length from commerce by employing an agent (National Museum of Victoria, 17 September 1900, 31 May 1901) By 1904, he declared that "business with the dealer fraternity is so unsatisfactory" that he was badly in need a larger pool of reliable correspondents Dispensing with middlemen, he now preferred to deal directly with collectors and museum personnel (National Museum of Victoria, 4 May 1904)

Once Dodd had turned commercial dealer, he encountered a host of rules and protocols governing selling, buying and gifting These activities were linked, not just to questions of honour and trust between correspondents, but to perceptions of social class and educational background (Lucas, 2013) There was, for instance, the delicate matter of promising certain correspondents first option on rare or large insects So great was the offence if these sought after insects were subsequently seen in others' collections that, if Dodd was planning to initiate a new contact, he would first ask permission from his established correspondents It was also bad form to share the secret of a special location without seeking permission For instance, Dodd claimed to be the first to let his mentor Rowland Illidge into the secret of where to find two species of the extremely valuable *Aenetus* (*A. ramsayi* Scott and *A. lewinii* Walker) outside Brisbane To Lyell he divulged "I was the first in Queensland to find and breed these and at once informed Illidge and we several times went out together I went away for 12 months + he took [Reggie] Relton into 'mateship' without consulting me". Illidge had also found *Aenetus* exuviae when out in the bush on his own and not let on to Dodd about his discovery Finally, Dodd liked a correspondent to give full details of unusual insects When it came to conveying such information, Oswald Lower, a pharmacist in Broken Hill, was one of the very slim ones, he complained Lower also offended Dodd by lacking an eye for beauty The closest he got to praising Dodd's settings, or a particular insect, was to ask him to "send another pair" Instead of such obliquity, Dodd preferred directness He liked correspondents "to express pleasure over a beauty or a rarity" "I get quite cross when I send away a lovely thing if the receiver does not 'enthuse' a little". Lyell must have remonstrated over these complaints about Lower and others

because Dodd conceded "You are right, biz is biz and I should get all I can As a seller it matters nothing to me what the buyer is like, I suppose (National Museum of Victoria, 12 August 1901, 6 July 1904)

As a commercial dealer Dodd touted his insects via several selling points Rarity, beauty and large size were chief So too, as we have seen, was endorsement by an expert classifier like Turner The other selling point was his talent as an insect breeder When circulating sale lists with prices, some pages contained a banner heading stating that all specimens had been bred In particular, he was proud of his high priced things, such as his Xylos, stuffed wood boring moths, bred and reared by him In his eyes these Xylos were perfect in every way With every skerrick of fat scrupulously removed, they were (he boasted) very unlikely to turn greasy (National Museum of Victoria, 17 September 1900) Dodd's letters also contain detailed descriptions of his breeding routines Sometimes he would watch all day until late at night for a large and rare wood boring moth to hatch Then, sleeping only for a few hours, he would wake to find his vigilance had been in vain his valuable moth had emerged and rubbed its wings Moths in the "restless" but "handsome" family of Notodontidae were particularly prone to offend in this regard, often emerging after he had retired (National Museum of Victoria, 24 March 1901) It was necessary to keep vigil in the bush as well, tending the larvae of insects for years before cutting and transporting the timber home for closer monitoring on the eve of emergence Sometimes, to Dodd's chagrin, local aboriginals ate the grubs he was watching over That these grubs were a traditional and highly nutritious food source for Indigenous people cut no ice with Dodd He was always very testy in his letters when mentioning this so called theft of his livelihood His son Walter D Dodd (1891 1965), also a naturalist, understood better than his father the symbiosis between Indigenous people and country From Walter Dodd's observations, it was clear that customary ways of living on country entailed a balanced economy of nature Writing about some very large wood moths he had caught south east of Perth in 1912, he noted that "The blacks were very fond of 'the grub'" Captive to the prevailing discourse surrounding the "inevitable dying out" of the Aboriginal race, Walter Dodd added that since indigenous people had become extinct in certain localities, "whole patches of wattle forests were laid low, there being no check upon the breeding of these insects" (*The North Queensland Register*, 13 April 1935)

The highest priced moth Dodd ever offered for sale was *Aenetus mirabilis* Rothschild, a species found only in north Queensland (fig 4) His excitement at sourcing this large moth can be heard in his warning to certain favoured correspondents to "save up your pennies" for a pair (National Museum of Victoria, 26 November 1900) He had read about this moth in a journal article published by Walter Rothschild in 1894, in which the location was disclosed as Cedar Bay, North Queensland This was a very remote spot 40 kilometres south of Cooktown and accessible only by boat or by foot (Rothschild, 1894) Dodd spent weeks and "a great deal of time and trouble" searching for this moth, at a cost of over £60, so he was obliged to charge highly for it He assured

Lyell, one of the first collectors he contacted regarding his precious discovery, that *A. mirabilis* was unlikely to be found in private collections, or even in the British Museum or any Australian museum "for many a long day, unless through me" As for Lyell's hint that the Victorian Government's entomologist Charles French (1842 1933) owned an *A. mirabilis*, Dodd was dismissive, imagining that it must be a damaged specimen, not perfect like those now in his possession He asked that Lyell keep quiet about his discovery as demand for specimens was going to be strong, and Dodd wanted to prioritise overseas collectors because they would pay considerably higher prices than those fetched in Australia

At first, Dodd asked Lyell for 60 to 100 [£3 £5] per pair for *A. mirabilis.* This approximates to a price range of £350 £585, or AUD $660 $1100 in today's purchasing power, the wide range reflecting the size, condition and appearance of the insects Dodd believed this price range was fair and reasonable His justification lay in the relative pricing of *Aenetus ramsayi*, a species of *Aenetus* that he had managed to sell to English collectors for £4 £6 per pair, even though this moth had been known for a long time and was well distributed, unlike the rare and "very fine" *A. mirabilis A. ramsayi* was also smaller than *A. mirabilis*, the female of which averaged wing spans of 6 5 inches In the end, Dodd settled on a lower quotation of 55 to 75 per pair for Lyell, reducing the cost a little because he realised his friend would find it impossible to obtain such rarities if he "stuck at their money value" He asked Lyell not to mention this discount as he also planned to sell to his competitors (i e Australian collectors he disliked such as Lower, a member of the questionable dealer fraternity, National Museum of Victoria, 26 November 1900) Charles French was another he distrusted, telling Lyell that French had the nerve to ask for his precious Xylos but still hadn't sent on the beetles he owed him (National Museum of Victoria, 17 March 1901) Lyell, on the other hand, belonged to Dodd's category of reliable correspondents In fact, so reliable was Lyell that when, a few months later, wealthy clients had failed to send on remittances, Dodd asked him to pay up front before he had even despatched the specimen box (National Museum of Victoria, 4 February 1901) He also asked that Lyell pay him a little every month to help keep him afloat between transactions

When it came to selling his *A. mirabilis*, Dodd pitched his highest price to Lower £5 for a single pair In the end, he sold him a pair for £4, a price that he claimed pleased Lower very much Dodd himself was happy with the transaction Given Lower's wide network and authority in the field, this sale would prove a good advertisement for Dodd's insects (13 June 1901) In general, Dodd figured that it made good business sense to sell his *A. mirabilis* cheaper to Australian correspondents because this would advertise the perfection of his preservation techniques Despite this, Dodd held himself aloof and was never less than testy with most of the dealer fraternity, believing that his southern brethren were all down on him because, after 1900, he would only sell and not exchange his grand tropical species for anything they could supply (National Museum of Victoria, 12 August 1901)

Conclusion

In July 1910, G. A. Waterhouse travelled from Sydney to the Atherton Tableland for a week of collecting. Staying in the Kuranda Hotel, he spent a good deal of time with Dodd and his family who were warmly hospitable. From here, Waterhouse wrote to Lyell, describing his first impressions of Dodd. There was much to like about the man. He was clearly an immensely enthusiastic collector who generously lent his sons to visitors like himself for collecting trips. He was pernickety, though, a charge that Dodd would have been proud to acknowledge. In running his business, however, Waterhouse declared him unmethodical, with barely one per cent of his pinned insects labelled with dates. Where there were dates, he suspected that they were a "mere matter of recollection". His classifications were sloppy too, with "similar groups of insects   mixed up anyhow" (National Museum of Victoria, AB 369, 17 July 1910). From Dodd's correspondence with the English dipterist Colbran Wainwright in the same year as Waterhouse's visit, this somewhat cavalier attitude about details can be seen in his postscript to one specimen box. "The localities are roughly marked off on the lids of the cigar boxes. The next lot will be arranged better, and month of capture given" (Royal Entomological Society, 24 August 1910).

As Waterhouse's week in Kuranda neared the end, he informed Lyell that Dodd's "tourist business brings the most money" meaning that "attention to scientific detail suffers in consequence" (National Museum of Victoria, AB 369, 17 July 1910). By tourist business, Waterhouse was referring to Dodd's recent commercial initiative: the opening of his house to members of the public for an entrance fee. Before 1910, Dodd had always welcomed visitors curious to view his collections and see him at work, setting and preserving his specimens, but with entomology a full time business for supporting his large family, he decided to charge a fee for this. Here we see him in a three piece suit, posing in his garden with a butterfly net for one of his paying tourists (fig. 5). Dodd was quite the showman in this new business venture, an empresario who used special lighting effects and other tricks to impress his visitors with the mystery and beauty of his insects, turning his home into a semi

Figure 5. F. P. Dodd in his garden at Kuranda. Image courtesy of Queensland Museum.

public commercial site and museum. Into sober, scientific scrutiny, he injected an older element of spectacle and magic, performing his insects with dramatic exhibitions which mingled natural science, wonder and magic. This was the case even when his visitors were some of the top people in the field, such as Walter Baldwin Spencer and A. J. Gilruth, who visited in 1911.

Margaret Fountaine (1862–1940), a globe trotting British lepidopterist who had recently settled with her lover not far from Kuranda, left her own account of calling to see Dodd's collection in 1916. Waiving the usual admittance fee of one shilling each, Dodd greeted them heartily as fellow entomologists, and they had a delightful time taking tea and revelling in his exhibits. Fountaine was impressed by Dodd's knowledge of Britain's scientific scene. He had read her articles in the *Entomologist* and in the *Transactions of the Entomological Society of London*. After talking entomological shop for a while, Dodd tried, with a "shrewd, penetrating" look, to dissuade Fountaine from thoughts of farming in the area. He argued, as others had done, that her prospects of success were dim. As she left, she invited him to come over and see her Malay and Java butterflies, an idea that seemed to delight him, but it would not be for a week or so (he claimed) because he was so busy. Fountaine's diary entry concludes

> We both liked Mr Dodd very much, and I
> believe the old man wishes to be a good friend
> to us, especially as he sees that we are not going
> to be in any way rival dealers, which naturally,
> as he makes his living out of this business, he
> could not be expected to look upon with any
> favour (L. Joanne Green, personal
> communication, 30 June 2019)

Fountaine's own eye was shrewd and penetrating in concluding that their reception would not have been so friendly had they planned to set up as business competitors.

We have seen Dodd move from exchange to commerce, transacting a business in which there were no fixed prices to guide him in determining the value at which he should trade a specimen. Beauty, colour, size and rarity were key determinants of cost, but perhaps most important was the symmetry and neatness of the setting, allowing the specimens' natural attributes to be seen. Since he was well known for his personal skill in preserving specimens, he believed his reputation in this regard entitled him to charge extra. At first Dodd is uneasy about his new dealer persona, embarrassed to be treating his insects as commodities instead of exchanging them for pleasure. He also worried, at the outset, that seasoned dealers and collectors like Lower would see him as green and try to take advantage of him. But in general he regarded trade as honourable. He needed to get his insects out through the proper channels and did not see any of this as injurious to the pursuit of science. In sum, he was well above J. O. Westwood's definition of the very "lowest class of entomologists", a collector with inert drawers of "handsome insects".

Despite Dodd's many promises to Lyell, Kershaw and others that he would start to be more methodical in preserving dates and locations, as well as keep lists of his insects, he kept on failing to do so. As for keeping a collection of named

specimens to guide him, this would not only be too cumbersome but also beyond what he could afford (National Museum of Victoria, 1 June 1911). It is difficult to determine if his shortcomings regarding taxonomic identification negatively affected his pricing. Although many of the letters contain lists with prices attached, we see him in his correspondence attempting to establish equivalencies and differences in value from one specimen to the next. Isolation, doubts about identification and the difficulty of knowing for certain if one's captures were rare were all inhibiting factors. The best he could do was to offer the insects in as perfect a condition as possible, along with close observation of their life histories. How did he classify himself? In the end, Dodd saw himself, not as an entomologist but as a professional collector, training up his four sons to be useful, all round collectors across the various orders (National Museum of Victoria, 6 December 1912). One son, Alan Parkhurst Dodd (1896–1981), would in fact become a distinguished entomologist, collecting and importing live specimens of the *Cactoblastis* moth from Argentina to destroy the prickly pear that had spread over millions of acres of Queensland farmland. In Alan, F. P. Dodd's legacy lived on.

Abstract   Hearn, L R , Stevens, M L, Schwarz, M P and Parslow, B A 2021 Parasitoids of the uniquely social colletid bee *Amphylaeus morosus* (Hymenoptera· Colletidae) in Victoria *Memoirs of Museum Victoria* 80 183 191

Understanding how nest parasites contribute to brood mortality rates in host species is an important step towards uncovering the potential implications for host behaviour This can be especially important for understanding the evolution of social living, where defence against parasites is often posited as a major benefit of cooperative nesting Only two parasitoid species have previously been reported for the only known social colletid bee, *Amphylaeus morosus* the gasteruptiid wasp, *Gasteruption primotarsale*, and the mutillid, *Ephutomorpha tyla* Here we report six additional parasitoid species of *A morosus* the gasteruptiid wasps *G atrinerve*, *G globiceps*, *G. melanopoda* and *G. cinerescens*, the bombyliid fly *Anthrax maculatus*, and the mutillid wasp *Ephutomorpha* aff *varipes* The mechanisms of parasitism for these eight parasitoid species are described in combination with how they operate throughout the host brood rearing period and whether benefits of social nesting vary across the season

Keywords   Bombyliidae, Gasteruptiidae, host association, Hylaeinae, Mutillidae, parasitism

Introduction

Detailed host and parasite association data are important yet rarely explored for primitively social hosts, where defence against parasites is posited to be a driver of cooperative nesting For insect parasitoids, the value of this information is often emphasised but is heavily weighted towards key taxon groups, such as Ichneumonidae, Braconidae, Chalcididae, Encyrtidae, Tachinidae and Bombyliidae, that are of economic importance (Heraty, 2017) Entomophagous insect associations with non apid bees largely get overlooked but can have substantial consequences for brood mortality, behaviour and demography of host species (Segers et al , 2016, Smith et al , 2017) Additionally, parasite host interactions in bees are seldom observed over their full life history, meaning the full series of parasites attacking a single host is often understated In the small carpenter bees *Ceratina dupla* Say, 1837, and *C. calcarata* Robertson, 1900, Vickruck et al. (2010) reared a total of eight parasite species from brood cells after sampling nests across a six month period Weislo et al (2004) similarly sampled nests of the halictine bee *Megalopta genalis* (Meade Waldo, 1916) across one year and reported four brood parasites infiltrating nests

However, Smith et al. (2017) noted that the full effect these brood parasites may have on the social nesting of *M. genalis* is hard to fully assess due to insufficient field data For analogous species, the need for descriptive biological information combined with rigorous sampling across the colony life cycle is often needed to determine the true diversity and effect of brood parasitism

The Australian hylaeine bee, *Amphylaeus morosus* (Smith, 1879) (Colletidae Hylaeinae), is the only species in the hyper diverse bee family Colletidae that is unambiguously known to exhibit social nesting Social nesting in this species is very simple, with no known reproductive hierarchies or morphological differentiation between nestmates *Amphylaeus morosus* has a semelparous and univoltine life cycle and may form social or solitary nests within the same population (Spessa et al , 2000) In the Dandenong Ranges, *A. morosus* uses naturally abscissed dead fronds of the rough fern tree *Cyathea australis* to construct linear nests out of the pithy interior Like many hylaeine bees, *A. morosus* mass provision cells with a mixture of pollen and nectar before ovipositing into the cells

Spessa et al (2000) first reported a species of *Gasteruption* wasp, later identified as *Gasteruption primotarsale* Pasteels, 1957 (Gasteruptiidae) (Parslow et al.,

2020), attacking nests of *A. morosus* in the Dandenong Ranges, Victoria, while a species of mutillid wasp, *Ephutomorpha tyla* Hearn, Williams & Parslow, 2019 (Mutillidae), was recently reported entering nests late in the brood rearing season (Hearn et al., 2019) Spessa et al (2000) found that social nesting in *A. morosus* seemed to provide only minimal benefits in reducing parasitism by *G. primotarsale* However, that study did not consider possible defence benefits against other parasites, and indeed no other parasites were identified in that study *Gasteruption primotarsale* parasitises the earliest brood during nesting period and may therefore only explain potential benefits of social nesting during the early stages of brood provisioning Additionally, observations of *E. tyla* adults in the nest towards the end of brood rearing (Hearn et al., 2019) suggest that *E. tyla* may exploit the mature larvae of *A. morosus* towards the end of its nesting period It is important to understand the full suite of parasites that attack *A. morosus* because if these parasites operate at other times in the nesting period, that information will further our understanding of why social nesting in *A. morosus* persists until brood maturation. In south eastern Queensland, Houston (1969) reported a range of parasites and parasitoids attacking *A. morosus* nests, including the wasps *Agamerion pulchra* (Pteromalidae Cleonyminae), *Coelopencyrtus* spp (Encyrtidae), *Gasteruption* sp (Gasteruptiidae) and an acarid mite However, in the Dandenong Ranges, little is known about the full range of parasites that might be involved

Here, we identify eight different parasitoid species that attack *A. morosus*, including novel host records for the *Gasteruption* wasps *G. atrinerve* (Kieffer, 1911), *G. globiceps* Pasteels, 1957, *G. melanopoda* Pasteels, 1957, and *G. cinerescens* Schletterer, 1885, the bombyliid fly *Anthrax maculatus* Macquart, 1846 (Diptera Bombyliidae), and the mutillid wasp *Ephutomorpha* aff *varipes* (André, 1895). We examine the specific mechanisms of parasitism and eclosion timings of these parasitoids, which have been poorly understood It is important that the respective host associations are well documented to fully recognise how these multiple parasitoid species may influence the nesting behaviour of the only known social bee in the colletid family.

Materials and methods

Nest collections

Nests of *Amphylaeus morosus* were collected from naturally abscissed fronds that haphazardly fall around the base of the rough tree fern *Cyathea australis* R Br Domin These nests were collected in the Gembrook, Cockatoo and Marysville regions of the Dandenong Ranges, Victoria, Australia Nests were sampled over five collection periods 4 6 December 2017, 6 8 December 2018, 21 22 November 2019, 11 January 2020 and 27 February 2020 The collection region primarily consists of cool temperate montane habitat dominated by tall canopies of *Eucalyptus regnans* F. Muell and *E. viminalis* Labill, with a mixture of ferny, shrubby and grassy understories Nests were collected early in the morning, late in the afternoon or during periods of light rain when bees were inactive to ensure all colony members were present Nest entrances were sealed upon collection and all nests were stored in cool insulated boxes and transported to the laboratory where they were stored at 10°C until processed

Parasitism data

Nests were dissected lengthwise and the contents, including adult female *A. morosus*, immatures and nest parasitoids, were recorded Where possible, parasitised cells were carefully extracted from the nests and left to develop in Petri dishes at ambient room temperature Petri dishes were kept moist by occasionally spraying filter paper rectangles inside each dish with water Once the specimens had reached adulthood, defined as fully mature and mobile, they were placed in 99% ethanol for preservation and later identification For parasitoids, where the pupal stages form cocoons (e g Mutillidae), at least one pupal case from each nest was dissected in coordination with the nest being opened to determine the developmental stage of each immature

Not all the *Gasteruption* specimens were successfully reared to pupae or adulthood because developmental rates for *Gasteruption* species lagged significantly behind host maturation rates, due to this, the specific parasitisation rates for each *Gasteruption* species were unable to be determined Further, the scarcity of larval descriptions based on morphology for the genus *Gasteruption* made it impossible to discriminate species at the larval stage (Bogusch et al., 2018) Therefore, the parasitisation rates for each species are combined and treated at the genus level *Gasteruption*

Specimen identification

Specimens were examined using a Nikon SMZ1000 stereomicroscope at the South Australian Museum, Adelaide, Australia Images were taken using a Visionary Digital LK imaging system (Dun, Inc) with a Canon EOS 5DsR camera at Flinders University, Adelaide, Australia Images were produced using Zerene Stacker (Zerene Systems LLC) software and cropped and resized in Photoshop CS5

Material examined in this study were initially identified using the following keys *Amphylaeus morosus* specimens were identified using Houston's (1975) key to Australian hylaeine bees, *Gasteruption atrinerve*, *G. globiceps*, *G. melanopoda*, *G. primotarsale* and *G. cinerescens* were identified by B A Parslow (South Australian Museum) using Pasteel's (1957) key to the Australian *Gasteruption* and comparison with type material, *Ephutomorpha tyla* specimens were identified by L R Hearn by comparing specimens with type material held at the South Australian Museum, and *Anthrax maculatus* was identified by X Li (Florida Museum) Voucher specimens for the examined species have been deposited at the Melbourne Museum (Table S1)

DNA sequencing for the eight parasitoids of *A. morosus* was performed by the Canadian Centre for DNA Barcoding at the Biodiversity Institute of Ontario using standard protocols (Ivanova et al., 2006, Table S1)

Results

Nest architecture and composition

In the Dandenong Ranges, females of *A. morosus* construct their nests in dead abscissed fronds of the rough fern tree *Cyathea australis* by excavating the pithy interiors of the stems to create an unbranched linear tunnel Nests were on average 212 63 + 59 39 mm long (mean + standard deviation, *N* 156) with nest entrance diameters of 5 65 + 0 61 mm (*N*   52) In other regions, nests also occur in the dead flower scapes of *Xanthorrhoea* spp (L Hearn, personal observation) The tunnel is lined with a cellophane like material, a characteristic common to hylaeine bees, that is thought to act as a waterproofing and antimicrobial agent (Almeida, 2008) Provisioning of brood cells generally begins in mid spring, and cells are laid sequentially starting from the distal end of the fern frond towards the proximal end Brood production can last until mid summer across the Dandenong Ranges populations, allowing different parasitoid species to attack at different brood development stages (fig 1)

Nest architecture in *A. morosus* can be broadly categorised into nests with brood cells interspersed with vestibules and nests with brood cells laid sequentially (fig 2) Vestibules are empty spaces containing no provisions or brood and are common in many stem nesting Hymenoptera (Danks, 1971) In *A. morosus*, vestibular cells are frequently found in solitary nests, but nest burrows are fully excavated before the first cell is provisioned This limitation to nest length once cell provisioning has begun suggests that there may be a trade-off between the number of potential brood cells and constructing vestibular cells to deter nest parasitoids

Host associations

Gasteruption Latreille, 1796 (fig. 3a). *Gasteruption* is the most abundant parasitoid of *A. morosus* in terms of nests parasitised, parasitising 16 9% (27 160) nests across all collection periods (Table 1) Of the nests parasitised by *Gasteruption*, only the first three brood cells were found to contain parasitoid immatures *Gasteruption* parasitised cells were often followed by vestibular cells (11/35 parasitised cells),

detritus (9 35) or provisioned cells that failed to develop (4 35).

The larvae of *Gasteruption* are predator inquilines in the nests of *A. morosus* where they kill the host egg or developing host larva before consuming the entire host provisions (Bogusch et al , 2018, Parslow et al , 2020) They then construct, using anal secretions, dark semi cocoons above and below the larvae separating the parasitised cell from the rest of the nest (Eardley and Daly, 2007, Malyshev, 1968, Westrich, 2018) Although some species of *Gasteruption* have been reported to consume the contents of multiple adjacent cells (Donovan, 2007, Malyshev, 1968, Westrich, 2018), *Gasteruption* immatures were only observed to occupy a single host cell in our nests of *A. morosus*

Adult eclosion of *Gasteruption* occurred far later in the season compared with *A. morosus* (fig 4) In most cases, *Gasteruption* brood were still at a late larval stage at the time *A. morosus* cells were reaching adult eclosion Five species of *Gasteruption* were reared from host nests One of these, *Gasteruption primotarsale* Pasteels, 1957, has been previously recorded from nests of *A. morosus* (Spessa et al , 2000) The novel host association for *G. atrinerve* (Kieffer, 1911), *G. globiceps* Pasteels, 1957, *G. melanopoda* Pasteels, 1957, and *G. cinerescens* Schletterer, 1885, were determined using adults reared from host nests

Anthrax maculatus Macquart, 1846 (fig. 3d). Four nests were found to be parasitised by the bombyliid fly *Anthrax maculatus* across two separate sampling periods *Anthrax maculatus* was never directly observed ovipositing into or hovering around the nests of *A. morosus* Yet, developing *A. maculatus* immatures were found occupying both single and consecutive *A. morosus* brood cells, accounting for 24 1% (7 29) and 13 8% (15 109) of the total brood cells across the early summer (December 2018) and mid summer (January 2020) collection periods, respectively The pupae of *A. maculatus* were primarily observed occupying cells in the middle of the nests, but in one instance, every cell in the nest contained parasitised immatures All brood cells parasitised by *A. maculatus* contained late stage pupae when the nest was opened, and in nests containing both *A. maculatus*
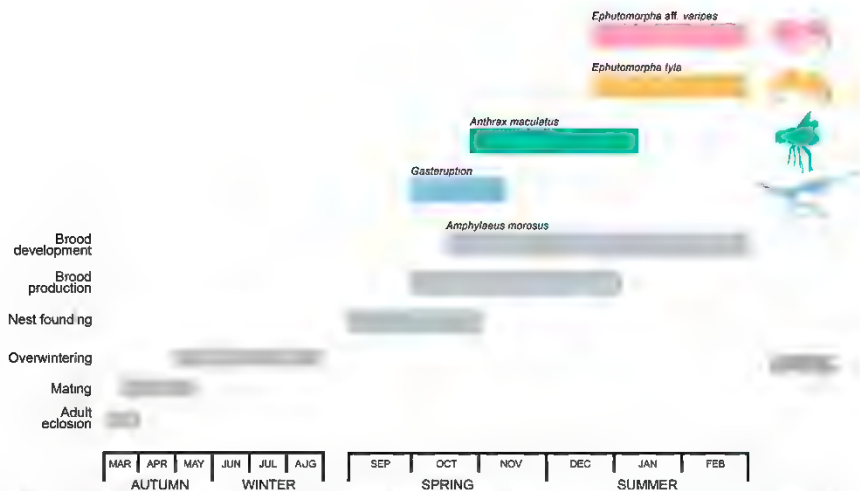

Figure 1 Annual cycle of *Amphylaeus morosus* across the fully univoltine, semelparous life cycle in the Dandenong Ranges, Victoria (grey). The timings of nest parasite attacks (coloured) were estimated from rates of occurrence in nests across the brood development period

Figure 2 Nest dissections showing the two typical nesting structures for *Amphylaeus morosus* in the Dandenong Ranges. a typical structure of a solitary nest, b close-up of brood cells directly followed by a pithy cell plug interspersed with vestibular cells, c typical structure of a social nest, d close-up of brood cells laid sequentially. Scale bar = 10 mm
Figure 3. Images of the parasitoids reared from *Amphylaeus morosus* nests: a. lateral habitus of *Casterupson globiceps*; b. lateral habitus of *Ephutomorpha* sp.; c. lateral habitus of *Ephutomorpha* aff. *varipes*; d. lateral habitus of Anthrax maculatus e. *Ephutomorpha* aff. *varipes* larvae feeding on *A. morosus* pupae (photo credit James Dorey 2020). Scale bar = 10 mm.

immatures and unparasitised host immatures, the host brood cells contained mid- to late-stage pupae. The pupae of *A maculatus* were packed into the host brood cells and eclosed to adults within minutes of being extracted from the brood cell in the nest. The emergence of adult *A maculatus* therefore appeared to be stimulated by disturbance but still synchronised with host adult eclosion (fig. 4).

***Ephutomorpha tyla* Hearn, Williams, and Parslow, 2019 (fig. 3b).** The host association for *Ephutomorpha tyla* has already been described by Hearn et al. (2019). Here, we present additional details based on new data. In two nests, a single adult female *E. tyla* was observed trying to break through the most proximal cell in the nest, while in a further 21 instances, adult females were observed waiting in the nest entrance. *Ephutomorpha tyla* does not appear to specifically target certain nest types, attacking nests with up to 14 brood cells or nests with only four brood cells interspersed with vestibules. A total of 29 nests contained either parasitised immatures, an adult female *E. tyla* in the entrance, or both. No adult female *A morosus* were present in 69% (20/29) of these nests.

Parasitised brood cells consisted of brown papery cocoons that occupied the entirety of the brood cell. As the *E. tyla* immatures developed, the brood cells became darker and increasingly difficult to open. In nine affected nests, all brood cells were parasitised by *E. tyla*, with damaged partitions between cells. The body sizes of male and female *E. tyla* were generally consistent. However, in some cases there were marked differences in body size within each sex.

***Ephutomorpha* aff. *varipes* (André, 1895) (fig. 3c).** Larvae of *Ephutomorpha* aff. *varipes* were observed as external parasitoids of the mature larvae, prepupae and pupae of *A morosus* and were observed feeding on young pupae (fig 3e). Larvae of *E.* aff. *varipes* remained on their host until mature before producing a light brown silk-like cocoon and eclosing as an adult. The ectoparasitoid larva of *E.* aff. *varipes* were observed on multiple consecutive *A morosus* immatures in one nest. The first three brood cells of the parasitised nest contained fully healthy *A morosus* immatures, whereas the next eight brood cells were occupied by parasitised larvae, all of which eclosed as males. *Ephutomorpha* aff. *varipes* was observed

Figure 4 Eclosion phenologies of *Amphylaeus morosus* and its nest parasites. Emergence observations are only reported for the provisioning and rearing phase during 2019. Host emergences are only reported for nests containing parasitised brood.

parasitising several species that occupy excised *Cyathea australis* fronds, including another mass provisioning bee, *Hylaeus* sp, and a crabronid wasp, *Pison* sp While, on numerous occasions, females were observed in the nest entrance of the allodapine bee, *Exoneura robusta* Cockrell, 1922, no parasitic association has been confirmed

Other enemies

Of the 243 potentially viable *A. morosus* nests collected, 34 2% (83 243) contained no *A. morosus* adults or brood cells and had been superseded or temporarily occupied by other insect species Twenty four of these nests were occupied by *Pison* sp (Hymenoptera Crabronidae), two nests were occupied by the pteromalid wasp of the genus *Eupelmophotismus* (Hymenoptera Pteromalidae), while one nest contained recently eclosed encyrtid wasps from the genus *Coelopencyrtus* (Hymenoptera Encyrtidae) Five nests contained clerid beetle larvae (Coleoptera Cleridae), including two instances of nests with *A. morosus* immatures and adults that contained beetle larvae in the nest entrance

Discussion

Nest parasitoids are known to have detrimental effects on the survival and productivity of bees (Vickruck et al , 2010, Wcislo et al , 1994) Of the parasitoid species that attack *A. morosus*, the predator inquilines of the genus *Gasteruption* were the most prevalent, but least detrimental, only parasitising a mean of 1 29 cells per infiltrated nest, with 16 9% of nests being infiltrated We never observed *Gasteruption* entering nests of *A. morosus*, possibly because our nest collections were restricted to cool weather conditions when insect activity was low, it is likely that *Gasteruption* wait for the adult bee to leave before infiltrating the nest and ovipositing in an open brood cell (Macedo et al , 2012, Parslow et al , 2020) Parasitisation by *Gasteruption* was only observed in single female nests, which suggests that multifemale nests are guarded by one female while other individuals collect provisions, restricting the opportunity for wasps to oviposit (Parslow et al , 2020) The extended development time of *Gasteruption* in *A. morosus* nests has been similarly reported in *Gasteruption brachychaetum* Schrottky, 1906a, larvae in nests of *Hylaeus* aff *guaraniticus* (Schrottky, 1906b) (Macedo et al , 2012) The resulting asynchrony in adult emergence between *Gasteruption* immatures and host could be attributed to delaying their eclosion until hosts have started establishing new nests, which may explain observations of *Gasteruption* pupae in overwintering *A. morosus* nests (L Hearn, personal observation) For *Gasteruption*, parasitising the distal nest cells could be a factor of this extended development period and avoiding being disturbed by emerging bees and other emerging parasitoids There is limited information on *Gasteruption* host specialisation, with a large proportion of records based on single observations (Parslow et al 2020) It is unlikely that *A. morosus* is the only host for *G. atrinerve*, *G. globiceps*, *G. melanopoda* and *G. cinerescens* because their distributions extend beyond the distribution of *A. morosus* (Atlas of Living Australia 2021; Parslow, 2020, Pasteels, 1957)

In contrast, parasitisation by the dipteran *Anthrax maculatus* had a greater effect when invading *A. morosus* nests, parasitising 5 5 brood cells on average across *A. maculatus* infiltrated nests Previous studies have suggested that adult bombyliid females identify a host nest and oviposit directly into the nest entrance (Bohart et al , 1960). However, there are also reports of adults ovipositing haphazardly onto the ground, leaving the planidium to search for a host nest (Yeates and Greathead, 2008) This latter scenario could be likely in the Dandenong Ranges given the high density of *A. morosus* nests that can occur It was unknown if the larvae of *A. maculatus* feed on both the immatures and provisions in a cell Gerling and Hermann (1976) reported early instar larvae of the bombyliid fly, *Xenox tigrinus* (Evenhuis, 1984) (previously *Anthrax tigrinus*), feeding on the pollen bread in *Xylocopa virginica* (Linnaeus, 1771) nests However, bombyliid fly immatures are also known to feed on the mature larvae of their hosts (Felicioli et al , 2017, Minckley, 1989) The delay in adult eclosion by *A. maculatus* compared with its host is consistent with observations by Minckley (1989) of *Anthrax xylocopae* (Marston, 1970) delaying emergence to synchronise with its host This is because adults are not able to break through the cell partitions and therefore must wait for hosts to emerge (Gerling and Hermann, 1976) This could explain why *A. maculatus* puparium in our current study appeared to be stimulated by disturbance when removed from their cells

In our study, *Ephutomorpha tyla* was the most abundant and destructive nest parasitoid in terms of both the number of brood cells parasitised and (potentially) adult hosts killed *Ephutomorpha tyla* was rarely observed in nests with an adult host present, supporting similar reports of mutillids forcefully removing or killing host guards before ovipositing (Brothers et al , 2000) Adult *E. tyla* were generally observed in the nest entrances and on some occasions attempting to break through the cell closest to the entrance, suggesting that *E. tyla* may open the brood cell closest to the entrance to check for host brood before ovipositing The size differences between reared adults of *E. tyla* are likely due to differences in the consumed host immatures For instance, in *A. morosus*, the males are generally smaller than the females (Spessa, 1999) Additionally, the amount of provisions in each brood cell can vary dramatically, which can influence the size of the host immatures and subsequently the ectoparasitoid feeding on it (Brothers, 1989) Comparatively, the size differences observed in adults of *E.* aff *varipes* support the notion that it is likely a parasitoid of multiple insect hosts, this accords with reports by Mickel (1928) that variation in body sizes within mutillid species is linked to them exploiting a range of hosts of varying size *Ephutomorpha* aff *varipes* was observed in nests of numerous different host species including the allodapine bee, *Exoneura robusta* Cockerell, 1922 However, given Brothers' Rule (Brothers et al , 2000), which states mutillids will only attack fully enclosed immatures, it is unlikely that such a condition is universal given that *E. robusta* progressively rears its brood in open linear nests These observations suggest that *E.* aff *varipes* is a generalist parasitoid of hosts using *Cyathea australis* as a nesting substrate, rather than any specific hymenopteran host, which accords with the notion that some mutillid species are adapted to specific situations rather than hosts (Brothers, 1989)

Attack by wingless parasitoids such as mutillid wasps is uncommon in stem nesting bees (Ronchetti and Polidori, 2020) Michener (1985) suggested that this may be because predators need to search in a three dimensional space looking for sparsely distributed nesting sites, whereas ground nesting hymenopteran entrances can be found using a two dimensional search pattern In *A. morosus*, the high rates of parasitism might be attributable to the high density of their nesting substrate around mature tree ferns (Groulx and Forrest, 2018) This high density of nesting sites may act in a similar system to the ground nesting aggregations of halictid bees, where nesting sites are abundant, and parasitism can be prevalent (Wcislo, 1996)

The mechanisms of parasitism and bionomy of parasitoids has generally been poorly understood. Our study finds that parasitoids of *A. morosus* have adapted to host nesting behaviour and suggests variation in the oviposition chronology of each parasitoid species, with *Gasteruption* wasps ovipositing at the beginning of brood provisioning, *A. maculatus* ovipositing across the middle stages of brood development and the two mutillid species ovipositing in nests at the end of the season This variation in parasitoid pressure could have implications for understanding the factors driving social nesting in the only known social bee in the family Colletidae

Abstract

McSweeney, F.R., Shimeta, J and Buckeridge, J S 2021 Early land plants from the Lower Devonian of central Victoria, Australia, including a new species of *Salopella Memoirs of Museum Victoria* 80 193 205

Early land plants with elongate sporangia held in the palaeobotanical archives of Museums Victoria were examined. The fossil plants are from Yea (?upper Silurian) and near Matlock (Lower Devonian) in central Victoria, and are of interest because they contribute to our understanding of the evolution of early land plants in a region in which research has been limited Both *Salopella australis* and *Salopella caespitosa* were originally described over 30 years ago and this reinvestigation has resulted in the emending of the diagnosis of *Salopella australis* and the erection of a new morphotaxon *Salopella laidae* sp nov based primarily on differing branching architecture and sporangial morphology *Salopella laidae* comes from Yea Formation and possesses regular isotomous branching over at least two orders of branching, terminating in elongate sporangia that are wider than their subtending axes, differing from *S australis*, which possesses only one dichotomy emanating from at least two erect parallel parent axes with sporangia that are the same width as their subtending axes A recently collected specimen of *Salopella caespitosa* was also examined and adds to our understanding of this taxon, which was previously only known from one specimen Consideration is given to the possible sources of these early land plants based on other early land plants with a similar grade of organisation

Keywords embryophytes, rhyniophytoids, *Baragwanathia* flora, Devonian, Victoria

Introduction

Fossil plants have been known in Victoria since the 19th century (Nicholas, 1875) Palaeobotanical studies on the *Baragwanathia* flora (Jaeger, 1966) from the Siluro Devonian of Australia have primarily been limited to the first half of the twentieth century (Cookson 1935, 1937, 1949, Lang and Cookson, 1927, 1930, 1935) and further expanded with Tims (1980), Tims and Chambers (1984) and McSweeney et al (2020) The majority of plant fossils have been uncovered in the Melbourne Zone (fig 1), and some further fragmentary remains have been found further south in the Mathinna Group of northeastern Tasmania (Baillie et al , 1989, Banks, 1962, Cookson, 1937, Powell et al , 1993) New data on early land plants from Australia, which was once part of northeastern Gondwana during the Siluro Devonian periods, is of significance globally because it allows comparisons between floral assemblages in Laurussia (Europe, the United States and Canada), mid palaeolatitude (Argentina) and high palaeolatitude (Bolivia and Brazil) western Gondwana sites and Chinese sites (North and South China Plates, Torsvik and Cocks, 2019) Furthermore, the new data allow for more

data to be acrued to test the hypothesis of a Lower Devonian northeastern Gondwana phytogeographic unit within which both South China and Australia were parts or subunits of, according to Hao and Gensel (1995, 1998, 2001) and Wang et al (2002)

This paper records one new taxon after an investigation of early land plant material with elongate sporangia collected by Tims and Chambers (1984) from the ?upper Silurian Lower Devonian Yea Formation, the Humevale Formation near Yea and the Lower Devonian Wilson Creek Shale Formation near Matlock in central Victoria (fig 1) Early land plants possessing elongate sporangia with tapering apices of either rounded or pointed tips and with fusiform or elongate parallel sided sporangia characteristic of rhyniophytes rhyniophytoids (*sensu* Edwards & Edwards 1986) were described by Tims and Chambers (1984) and assigned to *Salopella australis* and *Salopella caespitosa* The specimens described herein are compressions impressions with little anatomical detail preserved and belong to the same morphogenus *Salopella* Edwards and Richardson, 1974. One new specimen of *S. caespitosa*, only the second so far recorded, was also

examined and is of siginifcance to our understanding of this morphotaxon because it was preserved in semi relief as a coalified compression impression.

Locality, stratigraphy and age

The Melbourne Zone is a triangular stuctural region occuping central Victoria bounded by the Heathcote Fault in the west and Governor Fault in the east, opening towards the south (VandenBerg and Gray, 1988). The Wilson Creek Shale extends across the Melbourne Zone (VandenBerg, 1975; VandenBerg et al., 2006), and based on the conodont fauna, is considered to be middle Pragian–Emsian (Mawson and Talent, 1994). It comprises mudstone and shale units, characteristic of deep water and anoxic conditions, with *Uncinatograptus thomasi* (*Monograptus thomasi*) Jaeger, 1966, found throughout and *Neomonograptus*

notoaequabilis (*Monograptus aequabilis notoaequabilis*) Jaeger et al., 1969, in the upper half (Edwards et al., 1997, 1998, Lenz 2013; VandenBerg, 1988; VandenBerg et al., 2006). The outcrop examined occurs on Frenchmans Spur track, approximately 10 km west of Matlock, and is the type location of the rhyniophytoids *Salopella australis* and *S. caespitosa*, and the early "trimerophyte grade" (*sensu lato* Banks 1975) plant *Dawsonites subarcuatus* (Tims and Chambers, 1984).

The Humevale Siltstone and Yea Formation occur in the western part of the Melbourne Zone (Edwards et al., 1997, VandenBerg, 1988) and both are exposed near Yea. The dating of the exposures at Ghin Ghin Road and Limestone Road, Yea, as Pridolian and Ludlovian respectively by Garratt and Rickards (1984, 1987), Garratt et al. (1984), Rickards and Garratt (1990), and Rickards (2000) are contentious for a number of workers (Banks 1980, Cleal and Thomas, 1999,

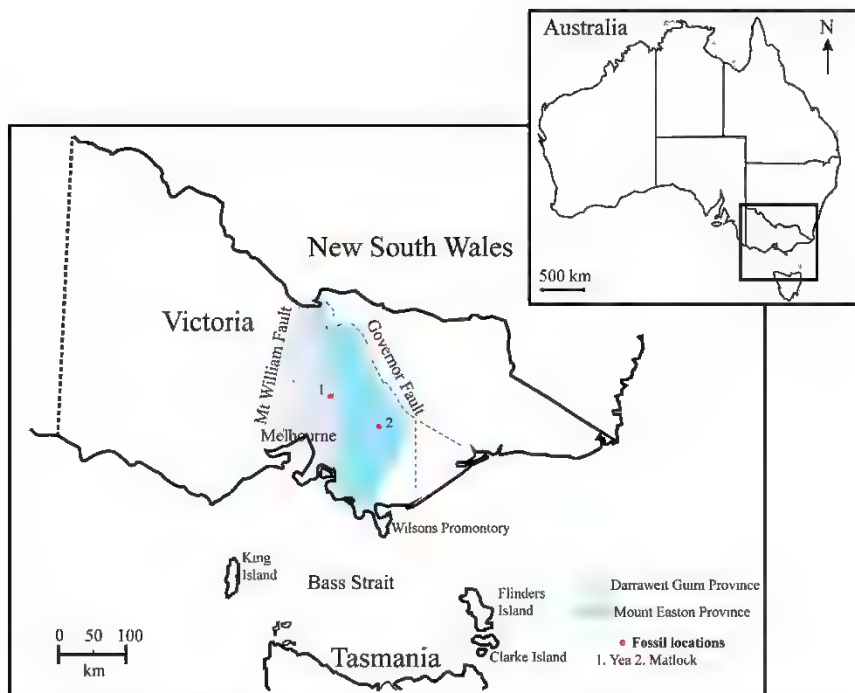

Figure 1 Map of Victoria Australia showing the fossil locations within the Melbourne Zone. Location 1 Yea Ghin Ghin Road Limestone Road 37° 12 38 S 145° 25 39 E) Location 2 Matlock Frenchmans Spur 37° 25 82 S 146° 77 24 E the type location of *Salopella australis* and *S caespitosa* Tims and Chambers 1984. Source adapted from Moore et al. 1998 fig 2

Edwards et al, 1979, Edwards et al, 1997, Hao and Gensel, 2001, Hueber, 1983, 1992) Hueber (1983) considered the morphological and anatomical complexity of *Baragwanathia longifolia* more akin to a Lower to Middle Devonian age and noted the complex nature of the conspecific taxa *Yarravia (=Hedeia)* to further that point, McSweeney et al (2021) Hueber (1992) suggested differences between the *Baragwanathia* from the two horizons at Yea were likely intraspecific and considered the interpretation of graptolites by Garratt and Rickards (1984) as subjective because preservation was poor Additionally, Hueber (1992) highlighted that the purported 24 million year difference between the two horizons had resulted in little evolutionary change, as did Hao and Gensel (2001 103), yet massive differences occurred over 3 million years between the *Cooksonia* spp found in Ireland (Edwards et al, 1983) and the younger Lower Plant Horizon of Yea Edwards et al (1979 321) questioned the interpretation of the age of *Maoristrophia banksi* and the graptolites not occurring on the same plane as the *Baragwanathia* in the Lower Plant Horizon Finally, Edwards et al (1997 22) consider the Humevale and Yea Formations at Yea to be part of the Norton Gully Sandstone Formation.

The Yea and Humevale Formations espoused by Garratt (1978) are retained because they provide a stratigraphic framework for the area (McSweeney et al, 2020 fig 2 – stratigraphical comparison chart and Ghin Ghin Road exposure) However, a Lower Devonian age will be used when assigning an age to specimens at Yea to account for these differing interpretations

Materials and methods

The collection site of early land plants from Limestone Road, Yea, is heritage listed, with further collecting forbidden, in addition, the Frenchmans Spur locality is heavily overgrown and, for the most part, inaccessible. The specimens described herein are from Museum Victoria's palaeontological archives and were collected by J D Tims and J Douglas in the 1970s and early 1980s, and one specimen *S caespitosa* (NMV P235941) collected by C Earp and M Pepper, 19 m from the Devil's Elbow road cutting on Ghin Ghin Road, Yea, central Victoria, Australia

The specimens collected by Tims and Douglas are preserved as fine compressions impressions, and even after maceration with Schultze's solution and acetate film pulls (see Tims and Chambers, 1984 266), no evidence of internal anatomy remains The *S. caespitosa* collected by Earp and Pepper is coalified and a fragment was taken from the lowest part of the parent axis of NMV P235941 2 using a fine steel needle Additionally, a fragment was dislodged from the centre of the basal dark presumed sporogenous region of sporangia two and four on NMV P235941 1 These fragments were placed onto aluminium stubs for scanning electron microscope analysis under low vacuum on an FEI Quanta 200 ESEM at RMIT University's RMIT Microscopy and Microanalysis Facility (RMMF)

Images were taken at Museums Victoria (Carlton) using a Leica M205 C microscope and Leica Application Suite

software version 3 8 0 Images were edited using Adobe Illustrator CC 2017 and morphological measurements were taken using ImageJ software Dégagement was undertaken on the Museums Victoria material archived by Tims (1974, 1980), Tims and Chambers (1984) and J Douglas

Institutional abbreviations

NMV P, Museum Victoria Palaeontology Collection, Melbourne, Australia The use of 1 and 2 at the end of NMV P refer to part and counterpart, respectively All specimens including the samples placed on stubs for scanning electron microscope analysis are housed in the Palaeontological Section, Museums Victoria, Melbourne

Systematic palaeobotany

Plantae. *Incertae sedis*

Genus. *Salopella* **Edwards and Richardson, 1974**

Type Species *Salopella allenii* Edwards and Richardson, 1974
Salopella australis Tims and Chambers, 1984 (fig. 2A G, line drawing fig. 6A)
Salopella australis Tims and Chambers (1984: pl. 32, figs 1 6; pl 34, figs 4, 5, text fig 2A C)

Emended diagnosis (after Tims and Chambers, 1984) New information in bold Axes 0 9 2 4 mm wide with central line, **at least two long aligned parallel parent axes** with **one dichotomy each resulting in narrower shorter daughter axes terminated by a single sporangium on each.** Plant at least **80 mm high** No obvious branching at the base of the sporangia Sporangia 6 5 14 0 mm high and 1 3 2 0 mm wide, with parallel sides in the lower two thirds of the presumed fertile portion. Sterile sporangia apex tapering to a point in the upper third Spore characters unknown

Locality. Frenchmans Spur Track, 10 km west of Matlock, Victoria 37° 25 82' S, 146° 77 24' E

Stratigraphy and age. Wilson Creek Shale, mid Pragian Emsian, Lower Devonian (Carey and Bolger, 1995, Mawson and Talent, 1994)

Note Two specimens assigned to *S. australis* by Tims and Chambers (1984) from Limestone Road have been transferred to Gen et sp indet because the specimens are too poorly preserved to unequivocally assign to any taxon These are NMV P229617 and NMV P157323, NMV P157323 (Jack Douglas Private Collection) was figured by Tims and Chambers (1984 pl 32, figs 5, 6 and text fig 2b) but possesses a completely different branching architecture to the holotype for *S. australis* and has poorly defined sporangia Specimen NMV P157323 has been re drawn here (fig. 6B) for comparison to *S. australis* (fig 2A E) Specimen NMV P50011 from Limestone Road has been moved out of *S. australis* to a new *Salopella* species (see below) Most specimens assigned to the Wilson Creek Shale by Tims and Chambers (1984) on Frenchmans Spur track are considered *S. australis* because they have subtending axes the same width

as their sporangia (e g NMV P50014, NMV P33219 and NMV P50008 [holotype]) Only in cases where this character is equivocal are specimens assigned to Gen. et sp nov (e g NMV P50010)

Description. *Salopella australis* possessed an erect habit with at least two long parent axes aligned parallel to each other and with one distal dichotomy on each resulting in narrower shorter daughter axes, each terminating in an elongate sporangium with an acuminate apex A slight indentation occurs on some sporangia at the darker carbonaceous area and sterile interface, and proximally the dark carbonaceous area tapers inwards on the daughter axes

Remarks. A reassessment of the morphospecies *Salopella australis* as originally determined by Tims and Chambers (1984) has necessitated the removal of some of the specimens attributable to it, primarily due to differing branching architectures and poor preservation Tims and Chambers (1984 268) noted four species with two dichotomies, but only three were found, presumably, the fourth is in a private collection Nonetheless, all the specimens figured in Tims and Chambers (1984) were examined Tims and Chambers (1984 270) described *S. australis* as "open branched" (Tims and Chambers, 1984 pl 32, fig 5, 6) with at least two dichotomies of widely dichotomising daughter axes emanating from one parent axis, and up to at least 145 mm in length (fig 6B) However, this was found to occur on only three specimens from Limestone Road and was not found on the holotype (fig 2D, E double arrows between aligned parent axes)

The holotype possessed two aligned parent axes, with one of the parent axes dichotomising into shorter narrower daughter axes The other parent axis was not as well preserved However, another specimen with better preservation (fig 2A, C) shows both parent axes aligned and dichotomising into shorter narrower daughter axes terminated with elongate sporangia that are no wider than their subtending axes Tims and Chambers (1984 pl 32, fig 4) partly illustrated this specimen with only one of the parent axes shown However, Tims and Chambers (1984) did not mention or show the other parent axis aligned parallel to this axis Furthermore, there was an additional specimen in the collection not figured by Tims and Chambers (1984), likely due to its poor preservation, but which also had two aligned almost parallel axes and is similar to the holotype with two parent axes aligned and with one of the parent axes possessing a single dichotomy with short daughter axes terminated in elongate sporangia (fig 2B) Even taking into account the effects of degradation of the specimens before fossilisation and the effects of ocean currents on orientation of the axes, the Limestone Road specimens appears to have more in common with *S. caespitosa* than *S. australis*, with two dichotomies and relatively longer daughter axes from the ultimate dichotomy (fig 6B)

This emendation has resulted in the maximum known length of *S. australis* being reduced from 145 mm to 80 mm and the reduction of known dichotomies to one, with the sporangial dimensions and morphology remaining the same Specimens attributed to *S. australis* herein (fig 2A E) were

deposited in a deep marine quiescent environment of the Wilson Creek Shale, and like the holotype, possessed parallel erect axes This branching architecture of erect parallel aligned axes was found only in three specimens, including the holotype All the other specimens bar one, which is defined below, are too poorly preserved to attribute to any taxon Parsimony suggests that parallel axes that dichotomise at the same level, with axes of comparable widths, terminating in elongate sporangia on short daughter axes also of equal dimensions, that have been transported a considerable distance belong to the same plant (*sensu lato* Wang and Hao, 2004, Edwards et al , 2015, Edwards and Li, 2018a) and are representative of its true branching architecture We acknowledge that we have failed to show organic connection, and current alignment could conceivably result in this axial configuration, but the likelihood of this occurring to three separate specimens with characters such as branching and sporangia occurring at the same height and with the same dimensions is unlikely We postulate that the parallel aligned axes may have emanated from a rhizomatous region because there was no converging of the parent axes Two of these parallel aligned specimens were included in Tims and Chambers (1984) but noticeably in both cases, only one of the parent axes was visible (Tims and Chamber, 1984 text fig 2A, pl 32, figs 1, 2, 4) Additionally, the line drawing of *S. australis* in Tims and Chambers (1984 text fig 2a) shows the daughter axes of the parent axes with slightly differing lengths, which was based on Tims and Chambers (1984 pl 32, fig 1) But a closer examination of this specimen (holotype, fig 2D) shows the daughter axes are preserved on different levels of lamina, with the perceived shorter daughter axis (upper arrow) partly obscured by another axis

The specimens removed from *Salopella australis* (Tims and Chambers, 1984 pl 32, figs 3, 5) and placed in Gen et sp indet include isolated poorly preserved sporangia from both the Wilson Creek Shale on Frenchmans Spur (fig 2F, G) and specimens from Limestone Road because the preservations were generally poor and the branching architectures greatly differed to the holotype One of the excluded specimens (Tims and Chambers, 1984 pl 32, fig 3) with differing branching architecture to *S. australis* is described below as a new morphospecies Thus, *S. australis* is no longer represented in the flora of the Lower Plant Horizon.

Salopella caespitosa Tims and Chambers, 1984 (fig 3A–I (holotype) and fig. 4A–E)

Material· NMV P50016 (holotype) and NMV P235941 both with part and counterpart

The circumscription of *Salopella caespitosa* was based on a single specimen with its counterpart from the Wilson Creek Shale Formation on Frenchmans Spur Track approximately 10 km west of Matlock in central Victoria No new data have been added on this taxon since its inception The discovery of a new specimen from the base of the Humevale Formation on Ghin Ghin Road near Yea preserved in semi relief contributes information on its dimensions, gross morphology and temporal range
Figure 2 *Salopella australis* displaying parallel parent axes dichotomising into much shorter daughter axes that are terminated with elongate sporangia delineated with a constriction just above dark sporogeneous region. A .. from Wilson Creek Shale on Frenchmans Spur track 10 km west of Matlock. A erect parent axes parallel to each other dichotomising into two elongate sporangia from Wilson Creek Shale. Re-photographed here originally published in Tims and Chambers 1984 p 32 fig 4 and Tims 1980 fig 4 19). Specimen NMV P50014 B forked dichotomy terminated by sporangia from Wilson Creek Shale. And to the right hand side of the forked axis is another long axis which based on its orientation may also be part of the same plant. Constriction at arrow, lower arrow at dichotomy and double arrow at two aligned axes. Specimen NMV P33219 C close up of fructification in A sporangia barely extend beyond the confines of their subtending axes with slight constriction present above sporogeneous region at arrow. Specimen NMV P50014 D E holotype part and counterpart. On part constriction at arrow in sporangium. On counterpart, both parent axes are parallel to each other at dotted arrow. Re photographed here originally published in Tims and Chambers 1984 p 32 figs 1 2) Specimens NMV P50008 1 and NMV P50008 2 respectively F Gen et sp indet short daughter axes terminated in elongate sporangia. The cortex may be absent from subtending axes with only the central line visible. The lack of cortex prevents assigning to *S australis* as width of subtending axis to sporangia width is required. Originally photographed by Tims 1980 fig 4 13. Specimen NMV P50010 2 G *S australis* with two short daughter axes with constriction at arrow of the sporangium which is the same width as its subtending axis. Specimen NMV P202886

Description. The new specimen's length is 135 mm and consists of two synchronous dichotomies with longer than wide sporangia terminating each axis The naked slender axes are 0 8 1 8 mm wide, with the axial width decreasing equally after each dichotomy The first dichotomy occurs c 80 mm from the base of the fossil and c 31 mm from the second dichotomy (fig 4A at lower arrow) The subtending axes to the sporangia are 0 9 1 0 mm wide and 22 25 mm high with some slight variation in the width along all four axes and a slight narrower evident beneath sporangia three and four (fig 4B, the subtending axis to sporangium four pinches slightly about 1 mm below the sporangium) The sporangia are fusiform 1 5 2 0 mm wide and 4 8 6 0 mm high with the subtending axis slightly widening into the base of each sporangium The widest part of the sporangia occurs in the lowest quarter length, followed by a gentle tapering to rounded sporangial tips A sporangial wall is evident primarily but is not confined to the basal parts of the sporangia measuring 0 2 0 3 mm wide and is continuous with the subtending axes Sporangia two, three on the part and four on the counterpart possess what appears to be an infilled oval presumed sporogenous area, which are no greater than 1.2 mm wide and 1 5 mm high Sporangium four on the counterpart shows a fine linear cavity 0 15 mm wide entering the base of the sporogenous area and sporangium three on the part shows similar but larger opening beneath the sporogenous area, and beneath this is a fine central axis 0 1 mm wide, beneath sporangium two on the subtending axis, this axis is 0 2 mm wide Sporangium two (part) upper half possesses longitudinally oblique striations, 0 06 0 6 mm apart

Remarks Comparison to holotype The new specimen measures 50 mm longer than the holotype (fig 3), and its axial width is broadly in range with the holotype, which measures 1 1 1 9 mm wide according to Tims and Chambers (1984) What appears to be the widening of the parent axis in the specimen (fig 4A) is where the first dichotomy occurs, with the two daughter axes aligned for 26 mm before diverging for the remaining 5 mm before the second dichotomy From the holotype, the best examples of branching to compare to the specimen were found on the part specimen (right hand side) with isotomous dichotomies subtending sporangia one seven (fig 3A, fig 6D) Proximally on the axes ultimately terminate in sporangia one seven show the axes emanating from a horizontal axis This horizontal axis may represent part of a rhizomatous system or a distorted axis Tims and Chambers (1984) appear to have considered this a dichotomy because no other part of the fossil would give three dichotomies However, it is equivocal as to whether it is a distorted axis with a dichotomy Nonetheless, the axes of the new specimen examined are noticeably less flexuous than the holotype, for example, on the holotype axes leading to sporangia eight and nine showing changes in orientation of about 45° in conjunction with the daughter axes of dichotomies occurring at 10° and 45° These differences possibly represent differences in both current strength during deposition and the level of degradation of each of the plants There is a noticeable variation in the distance between the ultimate branching points and sporangia in the holotype, from c 6 mm as seen in sporangium 12, to c 26 mm

for sporangium seven, and up to at least 57 mm for sporangium eight, where the presumed branching point is not visible The axes decreased after each dichotomy, as noted by Tims and Chambers (1984), but with the specimen examined herein there is a much greater decrease in axial width after the first dichotomy Examination of the holotype did reveal a slight narrowing in the subtending axes (fig 3D F) of most of the sporangia (Tims and Chambers 1984 pl 34, fig 3), this was observed beneath two of the sporangia on the specimen, but in both cases may be artefacts of preservation, and more specimens are required to confirm this character

The size range of the sporangia in the holotype, 3 2 6 0 mm high and 1 3 2 0 mm wide (Tims and Chambers, 1984), is similar to the specimen examined herein, and both have a comparable average height to width ratio of 2 6 (Morris and Edwards, 2014 table 3) for the holotype and 3 2 herein The holotype shows slight variation in the location of the widest point of the sporangia, occurring either in the lowest quarter (fig 4F), like with NMV P235941 (fig 4C) or midway (fig 3D) The minor difference is possibly accounted for by the different types of preservation The specimen NMV P23591 shows these sporangial bodies in semi relief and indicate they were not flattened bodies Furthermore, examination of sporangia of the specimen revealed an oval presumed sporogenous region in the basal part of the sporangia, which is also present on sporangium 13 of the holotype (fig 3H) Tims and Chambers (1984 pl 33, figs 3 4) noted that on sporangium 13 of the holotype it may either be a double sporangium or dissociation of the sporangial wall giving the appearance of a double sporangium The evidence of a sporogenous area basally and relatively thick sporangial walls from the specimen examined herein (fig 4B) suggests either a crushed sporangium or stage of senescence pertaining to dehiscence Furthermore, some of the sporangia in the holotype have a darkened presumed sporogenous area completely filling insides of the sporangia (fig D F), which may have resulted from the breakdown of the wall holding the sporogenous area prior to fossilisation, as the sporogenous area occurs as a basal oval body on all sporangia of the specimen examined

Tims and Chambers (1984 pl 33, fig 3) found central lines of 0 2 mm diameter throughout the specimen, one of which was beneath sporangium 13 On the specimen NMV P235941, the central line was found to connect to base of the sporogenous region (fig 4B, C), which Tims and Chambers (1984) had postulated Tims and Chambers (1984) noted some axes of the holotype to dichotomise (c 6 0 mm) relatively close to the base of the sporangia (fig 3C), however, this was not the case with NMV P235941

The presence of longitudinal oblique striations on the upper half of sporangium two may reflect cell orientation and possible twisting as a means of dehiscence Obliquely orientated cells in the sporangia have been recorded for some *S. allenii* and absent for *S. marcensis* (Fanning et al, 1992, Morris and Edwards, 2014), and throughout the entire sporangia and subtending axes of *Tortilicaulis* (Edwards et al, 1994) There was no indication of twisting found for the subtending axes of the specimens' sporangia, suggesting it may only affect the upper part of the
Figure 3 *Salopella caespitosa* holotype from Wilson Creek Shale on Frenchmans Spur track 10 km west of Matlock. A, B part NMV P2029871 and counterpart NMV P2029872 respectively numbering follows Tims and Chambers 1984 p. 33 fig 1 Counterpart images are reversed to be in the same orientation as the part specimen A on right hand side of part specimen double isotomous dichotomies lead to sporangia one – seven Note at the arrows there is perpendicular branching that is suggestive of a rhizomatous system C sporangium 12 at the arrow there is another axis that is terminated in a sporangium that is partially visible Specimen NMV P2029871 D F Evidence of a slight constriction beneath sporangia at arrows D sporangia eight and nine on the left, Widest part of each sporangium occurring approximately midway along their length Note rephotographed originally published in Tims and Chambers 1984 p. 34 fig 3 Specimen NMV P2029871 E sporangium 22 is c 4 06 mm long and 1 4 mm wide The axis decreases from 1 2 mm proximally to 0 5 mm just beneath the sporangium Specimen NMV P2029872 F sporangia four right, and five both sporangia are slightly wider in the lower quarter of each sporangia Specimen NMV P2029872 G sporangium 22 appears to be two immature sporangia juxtaposed At arrow the apex rounded of the smaller fusiform sporangium is apparent Specimen NMV P2029871 H sporangium two lower arrow at axis surrounding presumed ovate sporogeneous area which reaches approximately halfway the length of the sporangium to the upper arrow Specimen NMV P2029871 I sporangium 13 arrows at axis surrounding sporangeneous area and upper arrow showing extent of ovate sporogenous body The axis does not recombine apically like in sporangium two suggesting it may have been crushed or hidden beneath the matrix Rephotographed originally figured by Tims and Chambers 1984 p. 33 fig 3 Specimen NMV P2029872

sporangia, however, this is conjectural. As noted by Morris and Edwards (2014: 42), sporangia containing spores are required for unequivocal identification and assessment of relationships. While the specimen described is three-dimensionally preserved, we believe erecting a new taxon to segregate it from the form genus would be premature and we should wait for more data. The presence of this specimen at the base of the Humevale Formation potentially suggests a late Silurian age (Rickards, 2000). However, as outlined in the stratigraphy section, we suggest a Lower Devonian age range for specimens found at Ghin Ghin Road until unequivocal evidence of age becomes available.

Figure 4. *Salopella caespitosa* NMV P235941 from Devils Elbow on Ghin Ghin Road northwest of Yea. A. overview of whole specimen NMV P235941 1. B. arrow Vt at vascular trace entering base of oval presumed sporogenous body of sporangium four and the subtending axis to sporangium four pinches slightly about 1 mm below the sporangium. Lower arrow at region where subtending axis is continuous with sporangial wall and upper arrow shows extent of sporangial body of sporangium three. Note for both sporangia the distal parts appear to be hidden in the matrix NMV P235941 2. C. lower arrow Vt at vascular trace entering base of oval sporogenous body with upper arrow at distal extent of sporogenous body on sporangium two on the counterpart. Note no longitudinally oblique striations are evident in upper half of sporangium but are evident on the part specimen NMV P235941 2. D. sporangium two at arrow longitudinally oblique striations on the upper half of the sporangium NMV P235941 1. E. close up of parent axis with longitudinal striations NMV P235941 1.

Salopella laidae McSweeney Shimeta and Blackeridge sp nov
fig 5A B fig 6D

Salopella australis Tims and Chambers 1984 p. 32 fig 3 text
fig 2C)

Diagnosis Plant at least 55 mm long, tuft branching architecture, with sporangia all reaching the same height, with naked dichotomously synchronous branched axes up to 3 2 mm wide basally and 13 mm below sporangia. Axial width decreases after each dichotomy Isotomous branching angles small, 30° 40° for the ultimate dichotomies and 15° 50° for basal dichotomies At least two orders of branching Branching 10.0 14 0 mm below sporangia. Eight sporangia, elongate sub fusiform 9 7 11 0 mm high and up to 2 5 mm at widest section in mid region, and wider than subtending axes, obtuse apices

Etymology Named for Mrs Peg Laid who kindly gave permission to collect fossil specimens from her property on Ghin Ghin Road, Yea.

Holotype NMV P500111 and NMV P500112, part and counterpart respectively, figured by Tims and Chambers, 1984 pl 32, fig 3 and text fig 2C

Locality Location 4, Brackley's cutting (Harris and Thomas, 1941) Limestone Road, 2 km southeast of Yea. Note: exposure referred to as locality 62 in Couper (1965) 37° 12 38' S, 145° 25 39' E

Stratigraphy and age Location 4 (Harris and Thomas, 1941 303) Yea Formation (Garratt 1978), Lower Devonian (Pragian, Edwards et al., 1997, Rickards, 2000, Rickards and Garratt, 1990)

Salopella laidae sp nov **(fig. 5A, B, fig. 6C)**

Description Specimen preserved as a faint white compression on blue grey claystone with six of the eight sporangia preserved. There is no clear sporogenous area within the sporangia. However, sporangia five, seven and eight (fig 6C) on the part (fig 5A) possess darkened creamy grey regions extending up two thirds of their lengths and possibly represent a sporogeneous region. No internal anatomy or spores were

Figure 5 *Salopella laidae* sp nov holotype NMV P500111 and NMV P500112 part and counterpart respectively with counterpart reversed to be in the same orientation as part specimen From location 4 Brackley s cutting on Limestone Road Yea A double isotomous dichotomy visible terminated with eight elongate sporangia five visible At lower arrow central line and at F folding of tissue On sporangium seven ?sporogenous region highlighted Rephotographed originally figured by Tims and Chambers 1984 p. 32 fig 3 and text fig 2C B arrow at daughter axis missing on part present

recovered when Tims and Chambers (1984) examined this specimen. The sporangia are slightly wider than the widths of their subtending axes and do not taper distally but come to a rounded apical region. There are two synchronous dichotomies clearly visible, with the axial width decreasing only after each dichotomy. Folding of tissue appearing as a longitudinal lineation along the edges of the axes and sporangia are visible; no evidence of dehiscence mechanism is present (fig. 5A).

Comments and comparison with other species. The diagnosis and description of this taxon is based on one specimen (part and counterpart). While we are mindful of issues in naming a new species on one specimen, we have done so because of the shape of the sporangia and compact branching architecture that set it apart from other rhyniophytoids (Table 1). The use of the paraphyletic genus *Salopella* (Edwards et al., 1994) is to emphasise its gross morphology and to follow previous workers (Tims and Chambers, 1984) in identifying Victorian flora. However, we note that work done by Edwards et al. (1994) on in situ *Salopella* spores demonstrated significant diversity, that can be difficult to ascertain because of convergence of some sporangial shapes (Edwards et al. 2001: 11), making assertions on palaeogeographic distribution and spread unwise without palynological evidence. Tims and Chambers (1984) originally assigned this specimen to *S. australis*, but *Salopella laidae* sp. nov. differs to *S. australis* in a number of its characters (fig. 6 – comparative line drawings of Australian *Salopella*). *Salopella laidae* sp. nov. possesses sporangia that are clearly delineated from their subtending axes, differing noticeably from coeval *S. australis* (fig. 2A–E) where the sporangia are as wide as their

subtending axes. Furthermore, the sporangia in *S. laidae* sp. nov. do not taper from half-way to one-third from their apices as in *S. australis*; instead, they hold their sporangial widths before terminating with rounded apices. While the sporangial apices appear obtuse, this cannot be assumed to have been the case in life, as Morris and Edwards (2014: 40) found when examining *S. allenii* that compressed specimens possessed rounded apices of varying degrees, except that one specimen of *S. allenii* that was preserved in 3D had a pointed apex. The parent axes leading to the ultimate dichotomy in *S. australis* are long, erect and aligned parallel to each other (fig. 2A), being easily distinguished from *S. laidae*, where the axes leading to the ultimate dichotomy are at an angle to the vertical. Furthermore, *S. australis* only possesses one dichotomy, while *S. laidae* possesses two, or possibly three, as suggested in Tims and Chambers (1984: text-fig. 2C). However, it should be noted the proximal axes of *S. laidae* sp. nov. are orientated away from each other, suggesting they may have come from a rhizomatous axis instead of a dichotomising one.

One of the parent axes of *S. laidae* sp. nov. is incomplete, but likely possessed four sporangia (fig. 6C). This is based on the relative dimensions, orientation and positions of both parent axes to each other, and that four sporangia terminate the daughter axes of the other parent axis.

The sporangia of *Salopella caespitosa* are ovate to fusiform and up to 6.0 mm high and 2.0 mm wide (Tims and Chambers, 1984), which is approximately half as high than *S. laidae*. Furthermore, the axes of *S. caespitosa* are more gracile than those of *S. laidae*, as the latter reached a maximum width of 1.9

Figure 6. Line-drawings of Victorian early land plants with longer than wider sporangia. **A,** *Salopella australis* from Wilson Creek Shale on Frenchmans Spur track, near Matlock. Specimen NMV P50014. **B,** Gen. et sp. indet. from Limestone Road, Yea. Originally placed in *S. australis* but branching architecture clearly differs. Specimen NMV P157323. **C,** *Salopella laidae* sp. nov. from Limestone Road, Yea. NMV P50011. **D,** *Salopella caespitosa* (holotype) from Wilson Creek Shale on Frenchmans Spur track, near Matlock. Specimen NMV P202987. **E,** *Salopella caespitosa* from Ghin Ghin Road, Yea. Specimen NMV P235941.

mm proximally and 1 mm beneath the sporangia, whereas for *S. laidae* axes were at least 3.2 mm proximally and 1.3 mm beneath the sporangia. In comparison to other *Salopella* globally, the sporangia of *S. marcensis* and *S. xinjiangensis* are much smaller than *S. laidae*, reaching a maximum length of 3.4 mm and 3.5 mm long, respectively, and both much narrower (Morris and Edwards, 2014: table 3). Moreover, the sporangia of *S. xinjiangensis* are tongue-shaped (Cai et al., 1993; Dou and Sun, 1983), but *S. marcensis* sporangia are similar in gross morphology to *S. laidae*, being elongate and tapered at their apices according to Fanning et al. (1992). *Salopella marcensis* are much smaller plant than *S. laidae*, reaching 6.38 mm high, while *S. laidae* reached at least 55 mm high (Fanning et al., 1992: 174). While disarticulation for *S. marcensis* during transport seems likely, the isotomously branched axes bearing the sporangia for *S. marcensis* are much smaller than for *S. laidae*, ranging 0.05–0.5 mm wide (Fanning et al., 1992).

In Fanning et al. (1992: fig. 35), there is a silhouette of *S. marcensis* that shows a sporangium occurring on a lateral axis below a further bifurcation, indicating in this case at least that sporangia did not necessarily occur at approximately the same level, as is the case with *S. laidae* sp. nov. Finally, the type species of *Salopella*, *S. allenii* possessed fusiform or spear-shaped sporangia (Edwards and Richardson, 1974; Morris and Edwards, 2014) – significantly different to those of *S. laidae* sp. nov.

Discussion

Edwards and Richardson (1974) established *Salopella* based on one Lochkovian specimen of *Salopella allenii* from Brown Clee Hill, Shropshire (England); they noted its affinities to Rhyniaceae and that *S. allenii* possessed axes with dimensions that were between the range seen for *Rhynia gwynne-vaughani* and *R. major* (= *Aglaophyton majus*), with sporangia similar to both but lacking internal anatomy as seen in the Rhynie chert specimens (Edwards et al., 2017). Various workers have hypothesised that rhyniophytes/rhyniophytoids occupied ephemeral ruderal terranes, such as wetlands and deltas, whereby the rhyniophytes/rhyniophytoids completed their life cycles over short periods (Edwards, 2003; Edwards and Davies, 1990; Morris et al., 2011; Raymond et al., 2006; Wellman et al., 2000), possibly with some forming dense monotypic stands, such as the well-preserved aligned axes found near a fossilised channel from the Lower Old Red Sandstone deposits of Brecon Beacons (Edwards and Fanning, 1985: 156). According to Lavender and Wellman (2002), Edwards and Richardson (2004), and Raymond et al. (2006), seasonal conditions would have suited the short life cycles of rhyniophytes/rhyniophytoids. The location of the Melbourne Zone c. 30° south of the equator during the Lower Devonian (Torsvik and Cocks, 2019: fig. 9) suggests that the terrestrial sources for these deposits were likely also influenced by a seasonal climate, suiting the short life cycle of rhyniophyte/rhyniophytoids.

Furthermore, Edwards and Richardson (2004), when investigating the Lower Devonian calcrete palaeosols on the Avalonian Terrane, proposed rhyniophytes/rhyniophytoids as likely pioneer taxa because they were found on calcrete palaeosols that had formed in unstable interfluvial areas, with more advanced coeval plants, such as the zosterophylls or lycopsids, inhabiting more stable terranes to better accommodate their longer life cycles (Wellman et al., 2000). According to Powell et al. (2003: 29), there was a gradual shallowing of marine facies from the western margins of the Melbourne Zone in the Darraweit Guim Province, and eastward movement of the shoreline during the upper Silurian–Lower Devonian, which may have provided similar unstable conditions for rhyniophytes/rhyniophytoids, because palaeocurrents at areas in Yea and Matlock indicate a west or southwesterly source from the western parts of Victoria, which was terrestrial at the time (Powell et al., 2003: 23). Edwards and Davies (1990: fig. 16.3) noted the decline of rhyniophytes/rhyniophytoids from Laurussian sites during the late Pragian and Emsian stages of the Lower Devonian, possibly due to the proliferation of zosterophylls early in the Devonian. It is possible the uplift of the Tabberaberan highlands towards the end of the Lower Devonian in Victoria (Powell et al., 2003: 32) may have provided ideal unstable conditions for rhyniophytes/rhyniophytoids into the Emsian but work on the palaeoflora from the Norton Gully Sandstone Formation has been limited.

Finally, there is a noticeable difference in the number of rhyniophyte/rhyniophytoid taxa from Yunnan, China, in what was once part of the South China Block located at and north of the equator during the Lower Devonian (Torsvik and Cocks, 2019: fig. 9a), and those found in the *Baragwanathia* floral assemblage. According to Hao and Xue (2013: fig. 5.3), rhyniophytes/rhyniophytoids make up a small percentage (c. 2.7%) of the taxonomic groups found in the Posongchong Flora. Recently, Edwards and Li (2018b) erected *Polycladophyton gracilis* and *Jiangyounia gengi* possessing a grade of organisation belonging to Rhyniophytina. However, *Salopella* specimens have not yet been recovered (Hao and Xue, 2013: 193), suggestive of some level of isolation between the two regions.

Conclusions

Defining taxa based on gross morphological characters alone has limitations because it excludes cryptic characteristics and likely results in one morphospecies encompassing a number of distinct species. However, this study and the work of Tims and Chambers (1984) has provided a morphological framework from which new Victorian taxa may be defined, providing an impetus for further research.
